Prismatic Analysis of Brexit (2016-2026): Three Interpretive Grammars Processing a Shared Empirical Field

A Methodological Application of R. Jazinski's Framework from "Silent Transitions: How Interpretive Grammars Process the Same World into Different Truths"

Executive Summary

This report applies R. Jazinski's Prismatic Analysis methodology to Brexit, examining how three distinct interpretive grammars—Sovereignty/Democratic Self-Determination, Economic Integration/Institutional, and Class/Distributional—process the same empirical signals into fundamentally different explanatory narratives. Over the decade from 2016 to 2026, Brexit has generated a rich empirical field: a 52%-48% referendum result, GDP decline of 6-8%, dramatic shifts in trade patterns, evolving migration flows, constitutional tensions in Northern Ireland and Scotland, declining institutional trust, and divergent sectoral impacts. Each grammar selects, weights, and integrates these signals according to its own internal logic, producing distinct causal chains and closures.

The Sovereignty Grammar reads Brexit as democratic self-correction against technocratic overreach, emphasizing popular will and recovered autonomy. The Economic Integration Grammar interprets it as institutional rupture with predictable efficiency losses and coordination failures. The Class/Distributional Grammar frames it as working-class rebellion against an economic settlement that concentrated gains among metropolitan elites while imposing costs on peripheral regions. By holding empirical input constant while rotating interpretive frameworks, this analysis reveals how the "same" Brexit becomes three different phenomena—not through factual disagreement, but through fundamentally different ways of organizing facts into meaning. This methodological exercise demonstrates that interpretive divergence on Brexit stems not from information deficits but from incommensurable analytical architectures.

1. Observation Field Declaration

Phenomenon: The United Kingdom's withdrawal from the European Union, initiated by referendum on 23 June 2016 and formally completed on 31 January 2020, with transition period ending 31 December 2020, observed through ten years of implementation and consequence (2016-2026).

Temporal Frame: 2016-2026, encompassing pre-referendum baseline (2015-2016), referendum campaign and immediate aftermath (2016), negotiation period (2017-2019), transition and initial implementation (2020-2021), and medium-term adjustment (2022-2026).

Geographic Scope: United Kingdom of Great Britain and Northern Ireland, with particular attention to constituent nations (England, Scotland, Wales, Northern Ireland), regional variations within England, and UK-EU border zones. The analysis encompasses both internal UK dynamics and UK-EU relational effects.

Why Interpretive Divergence: Brexit produces exceptional interpretive divergence because it simultaneously activates multiple incommensurable value systems and analytical frameworks. It is at once: (1) a democratic event (referendum, popular sovereignty, parliamentary process); (2) an economic restructuring (trade reorientation, regulatory divergence, market access changes); (3) a distributional conflict (regional winners/losers, class-based voting patterns, inequality effects); (4) an identity assertion (national sovereignty, cultural values, immigration control); and (5) an institutional rupture (40+ years of legal-economic integration unwound). No single analytical variable can capture this complexity, forcing observers to privilege certain dimensions while backgrounding others. The result is not disagreement about facts but fundamentally different constructions of what Brexit *is*.

Major Interpretive Communities:

1. Sovereignty/Democratic Self-Determination Community: Emphasizes popular will, democratic legitimacy, national autonomy, and constitutional restoration. Includes Leave campaign architects, sovereignty-focused legal scholars, democratic theorists, and portions of the political right emphasizing national self-governance. Characteristic sources include parliamentary sovereignty arguments, democratic mandate discourse, and border control advocacy [1], [2].

2. Economic Integration/Institutional Community: Emphasizes efficiency losses from disintegration, coordination costs, institutional interdependence, and market access. Includes mainstream economists, trade specialists, business organizations, and technocratic policy analysts. Characteristic sources include economic impact assessments, trade modeling, and institutional analysis of EU-UK arrangements [3], [4], [5].

3. Class/Distributional Community: Emphasizes inequality, regional disparities, working-class grievances, elite capture, and the political economy of globalization's winners and losers. Includes heterodox economists, economic geographers, sociologists of class, and left political economy scholars. Characteristic sources include analyses of "left behind" regions, deindustrialization, and class-based voting patterns [6], [7], [8].

These communities do not merely disagree about Brexit's desirability; they construct fundamentally different objects of analysis from the same empirical field.

2. Signal Set

Core Signals (Empirical, Documentable, Citable)

Signal 1: Referendum Result (52%-48%)

- Description: On 23 June 2016, 51.89% voted Leave, 48.11% voted Remain, on 72.2% turnout. England voted 53.4% Leave, Wales 52.5% Leave, Scotland 62% Remain, Northern Ireland 55.8% Remain [9].
- Type: Democratic/Political
- Source: Electoral Commission data, BBC analysis [9]

Signal 2: GDP Impact (-6% to -8% by 2025)

- Description: By 2025, Brexit reduced UK GDP by 6-8% compared to counterfactual EU membership, with impacts accumulating gradually rather than as sudden shock [3].
- Type: Economic/Aggregate
- Source: Bloom et al. (2025) NBER working paper, Stanford SIEPR analysis [3]

Signal 3: Trade Volume Shifts

- Description: By Q4 2021, UK goods imports from EU down 18% vs 2019, exports to EU down 9%, while non-EU imports up 10%. Services trade with EU fell more than non-EU trade. By 2022, UK trade underperformed peer economies [10].
- Type: Economic/Trade
- Source: Office for Budget Responsibility, ONS data [10]

Signal 4: Investment Decline (-12% to -18%)

- Description: Brexit reduced UK investment by 12-18% by 2025, driven by elevated uncertainty, reduced demand, diverted management time, and increased resource misallocation [3].
- Type: Economic/Capital
- Source: Bloom et al. (2025), Decision Maker Panel survey [3]

Signal 5: Net Migration Reversal

- Description: Net migration 204,000 in year ending June 2025 (similar to 2010s levels but down from 2022-23 peaks). EU net migration turned negative: -70,000 in year ending June 2025. Non-EU migration increased substantially [11].
- Type: Demographic/Social
- Source: Migration Observatory, ONS provisional data [11]

Signal 6: Northern Ireland Protocol/Windsor Framework

- Description: Northern Ireland Protocol (2020) created regulatory border in Irish Sea, generating unionist opposition. Windsor Framework (2023) modified arrangements, implemented January 2025, with MHRA taking UK-wide responsibility for medicines but maintaining two-category system for NI [12].
- Type: Constitutional/Institutional
- Source: UK government guidance, academic analysis [12]

Signal 7: Scottish Independence Polling

- Description: Scottish independence support fluctuated 2016-2026, reaching 51% Yes in some 2025 polls (Ipsos: 51% Yes, 49% No, December 2025), though with high volatility and no sustained majority [13].
- Type: Constitutional/Political
- Source: Ipsos, YouGov, Wikipedia polling aggregation [13]

Signal 8: Institutional Trust Decline

- Description: British Election Study showed proportion with low-to-no trust in MPs rose from 54% (2014) to 76% (2024). Parliamentary trust indicators showed sustained decline post-referendum [14].
- Type: Political/Legitimacy
- Source: Parliamentary Office of Science and Technology, British Election Study [14]

Signal 9: Employment Effects (-3% to -4%)

- Description: Brexit reduced UK employment by 3-4% by 2025, with productivity declining 3-4%. Service sector job losses persisted through 2026 despite output growth [3].
- Type: Economic/Labor
- Source: Bloom et al. (2025), S&P Global PMI data [3], [15]

Signal 10: Sectoral Divergence

- Description: Manufacturing PMI reached 18-month high (52.0) by February 2026 with export order surge, while services showed more modest growth. Financial services faced market access challenges. Agrifood sector in Northern Ireland particularly affected by regulatory complexity [15], [16].
- Type: Economic/Sectoral
- Source: S&P Global PMI, industry analyses [15], [16]

Signal 11: Regulatory Divergence

- Description: UK-EU regulatory alignment decreased post-2021, with divergence in medicines regulation (Windsor Framework two-category system), financial services rules, and product standards, creating compliance costs [12], [17].
- Type: Institutional/Regulatory
- Source: Academic analyses, government guidance [12], [17]

Signal 12: Regional Voting Patterns

- Description: Leave vote concentrated in post-industrial regions, coastal areas, and areas with lower educational attainment. London, Scotland, Northern Ireland voted Remain. Nine areas voted >70% Leave (Boston, South Holland, Great Yarmouth, etc.) [9].
- Type: Political/Geographic
- Source: BBC analysis, Lord Ashcroft polling [9], [18]

Signal 13: Age and Education Gradients

- Description: 73% of 18-24 year-olds voted Remain vs 40% of 65+. 68% of university graduates voted Remain vs 32% of those with GCSE or lower [18].
- Type: Demographic/Social
- Source: Lord Ashcroft post-referendum poll [18]

Signal 14: Cultural Attitude Correlations

- Description: Remainers saw multiculturalism, feminism, Green movement, globalization, immigration as forces for good (large majorities). Leavers saw same forces as forces for ill (even larger majorities). 73% of Remainers thought life better than 30 years ago; 58% of Leavers thought it worse [18].
- Type: Cultural/Attitudinal
- Source: Lord Ashcroft post-referendum poll [18]

Signal 15: Productivity Stagnation

- Description: UK productivity declined 3-4% due to Brexit by 2025, reflecting resource misallocation, reduced economies of scale, and disrupted supply chains [3].
- Type: Economic/Efficiency
- Source: Bloom et al. (2025) [3]

Counter-Signals (Complicating Dominant Narratives)

Counter-Signal 1: Manufacturing Export Recovery

- Description: By February 2026, UK manufacturing reported fastest export order growth in 4.5 years, with broad-based upturn from US, Europe, and Asia, suggesting adaptation and new opportunities [15].
- Type: Economic/Trade
- Source: S&P Global PMI [15]

Counter-Signal 2: Non-EU Immigration Increase

- Description: While EU migration turned negative, non-EU immigration increased substantially, suggesting Brexit did not reduce overall immigration but changed its composition [11].
- Type: Demographic/Social
- Source: Migration Observatory [11]

Counter-Signal 3: Narrow Referendum Margin

- Description: 52%-48% result represents deeply divided electorate, complicating narratives of clear democratic mandate or popular consensus [9].
- Type: Democratic/Political
- Source: Electoral Commission [9]

Counter-Signal 4: Economic Forecasting Accuracy

- Description: Contemporary forecasts accurately predicted 5-year impacts but underestimated decade-long effects, suggesting both vindication and limitation of economic modeling [3].
- Type: Methodological/Epistemic
- Source: Bloom et al. (2025) [3]

Counter-Signal 5: Scottish Independence Polling Volatility

- Description: Despite Brexit, Scottish independence support has not achieved sustained majority, fluctuating around 50% with high volatility, complicating constitutional crisis narratives [13].
- Type: Constitutional/Political
- Source: Polling aggregation [13]

---

3. Grammar Specifications

Grammar 1: Sovereignty/Democratic Self-Determination Grammar

Grammar Name: Sovereignty/Democratic Self-Determination Grammar

Primary Analytical Variable: Democratic legitimacy and popular sovereignty

Signal Selection Rules:

- Prioritize signals demonstrating popular will expression (referendum results, voting patterns)
- Emphasize signals showing recovered national autonomy (border control, regulatory independence)
- Select signals indicating democratic accountability restoration (parliamentary sovereignty, devolution tensions)
- Foreground signals of constitutional significance (Northern Ireland Protocol, Scottish independence debates)
- Background purely economic efficiency measures unless they relate to democratic control

Weighting Priority:

1. Referendum result and voting patterns (highest weight)
2. Constitutional arrangements and sovereignty questions
3. Immigration control and border management
4. Institutional trust and democratic legitimacy
5. Economic impacts (lowest weight, relevant only as context for democratic choice)

Causal Chain Type: Normative-restorative. Brexit is caused by democratic deficit under EU membership and causes restoration of popular sovereignty, with economic costs as acceptable price of democratic self-governance.

Admissible Closure: Brexit represents democratic self-correction, where a sovereign people reclaimed control over laws, borders, and money from technocratic institutions insufficiently accountable to national electorates. Short-term economic costs are subordinate to long-term democratic gains.

Excluded Signals: Aggregate economic efficiency losses, productivity declines, trade volume reductions (except where they demonstrate recovered autonomy). These are acknowledged but not weighted as primary explanatory variables.

Characteristic Vocabulary: "Taking back control," "popular will," "democratic mandate," "parliamentary sovereignty," "accountability," "self-governance," "national autonomy," "border control," "independence," "constitutional restoration"

Source Tradition: Democratic theory, constitutional law, political philosophy emphasizing popular sovereignty, nationalist political thought, parliamentary supremacy doctrine [1], [2], [19], [20]

Grammar 2: Economic Integration/Institutional Grammar

Grammar Name: Economic Integration/Institutional Grammar

Primary Analytical Variable: Economic efficiency and institutional interdependence

Signal Selection Rules:

- Prioritize signals measuring economic costs and benefits (GDP, trade, investment, productivity)
- Emphasize signals showing institutional coordination challenges (Northern Ireland Protocol, regulatory divergence)
- Select signals demonstrating market access and integration effects
- Foreground aggregate economic outcomes over distributional effects
- Background cultural and identity signals unless they affect economic behavior

Weighting Priority:

1. GDP impact and aggregate economic performance (highest weight)
2. Trade volumes and investment flows
3. Productivity and efficiency measures
4. Institutional arrangements and regulatory alignment
5. Democratic legitimacy claims (lowest weight, treated as political constraint on economic optimization)

Causal Chain Type: Functional-efficiency. Brexit is caused by political miscalculation and causes predictable economic losses through disintegration of efficient institutional arrangements, with costs accumulating over time.

Admissible Closure: Brexit represents economically suboptimal institutional rupture, where political forces overrode economic rationality, producing predictable efficiency losses, coordination costs, and reduced market access. Democratic choice does not negate economic consequences.

Excluded Signals: Cultural attitudes, identity politics, distributional grievances (except as they affect aggregate economic outcomes). These are acknowledged as political context but not as primary analytical variables.

Characteristic Vocabulary: "Economic integration," "market access," "trade barriers," "efficiency losses," "institutional interdependence," "coordination costs," "regulatory alignment," "productivity," "counterfactual," "optimal policy"

Source Tradition: Neoclassical and new institutional economics, trade theory, European integration studies, technocratic policy analysis [3], [4], [5], [10], [21]

Grammar 3: Class/Distributional Grammar

Grammar Name: Class/Distributional Grammar

Primary Analytical Variable: Distributional consequences and class conflict

Signal Selection Rules:

- Prioritize signals revealing winners and losers (regional voting patterns, sectoral impacts, inequality effects)
- Emphasize signals showing class-based political behavior (education/age gradients, "left behind" regions)
- Select signals demonstrating elite vs. popular interests (institutional trust decline, cultural attitude divides)
- Foreground regional disparities and uneven development
- Background aggregate economic measures unless they reveal distributional patterns

Weighting Priority:

1. Regional and class-based voting patterns (highest weight)
2. Distributional economic impacts (sectoral, regional, occupational)
3. Cultural attitude correlations with economic position
4. Institutional trust decline among working class
5. Aggregate GDP (lowest weight, relevant only for distributional analysis)

Causal Chain Type: Structural-conflictual. Brexit is caused by distributional conflicts within neoliberal globalization and causes redistribution of political power from metropolitan elites to peripheral working class, with uncertain economic redistribution.

Admissible Closure: Brexit represents working-class rebellion against an economic settlement that concentrated gains among metropolitan, educated, professional classes while imposing costs (deindustrialization, wage stagnation, precarity) on peripheral regions and working-class communities. The vote was rational response to material grievances, not cultural backlash or misinformation.

Excluded Signals: Abstract sovereignty claims divorced from material interests, aggregate efficiency measures that obscure distributional effects, technocratic institutional arrangements that lack class analysis. These are acknowledged but reinterpreted through distributional lens.

Characteristic Vocabulary: "Left behind," "inequality," "working class," "elite capture," "regional disparities," "deindustrialization," "distributional conflict," "winners and losers," "economic grievances," "peripheral regions," "metropolitan elites"

Source Tradition: Political economy, economic geography, class analysis, heterodox economics, sociology of inequality [6], [7], [8], [22], [23]

---

4. Signal Processing

4.1 Sovereignty/Democratic Self-Determination Grammar

Processing the Signal Set Through Democratic Legitimacy

The Brexit phenomenon, when processed through the Sovereignty/Democratic Self-Determination Grammar, emerges as a profound democratic event: the largest exercise of direct popular sovereignty in British history, in which 17.4 million citizens voted to restore national self-governance after four decades of pooled sovereignty within supranational institutions. The referendum result (Signal 1) stands as the grammar's foundational signal, weighted most heavily because it represents unmediated popular will. The 52%-48% outcome, while close, exceeded the threshold for democratic legitimacy established by the referendum itself—no supermajority requirement was imposed, and the result was accepted as binding by all major political actors at the time [9]. The geographic pattern of the vote reveals not fragmentation but rather the reassertion of England and Wales's democratic weight within the Union, with Scotland and Northern Ireland's Remain votes reflecting their distinct constitutional positions but not negating the UK-wide democratic decision.

The referendum's legitimacy derives from its character as a direct democratic intervention into a question that had never been put to the British people with full knowledge of EU membership's implications. The 1975 referendum occurred before the Single European Act, Maastricht Treaty, and Lisbon Treaty—before the EU became a quasi-federal entity with its own currency, parliament, court, and expanding competences. By 2016, the EU had evolved far beyond what British voters had originally endorsed, creating a democratic deficit: major constitutional changes had occurred through elite-level treaty negotiations without popular

consent [1]. The Leave vote thus represents democratic correction, a people reclaiming sovereignty that had been progressively transferred without their explicit authorization.

The age and education gradients in voting (Signal 13) are, within this grammar, not evidence of ignorance or irrationality but rather of different democratic priorities. Older voters, having experienced both pre-EU and EU Britain, possessed comparative knowledge that younger voters lacked. Their preference for Leave reflected informed judgment about sovereignty's value, not nostalgia or xenophobia. Similarly, the education gradient reflects not superior Remain voter intelligence but rather different stakes: university-educated professionals in London and other metropolitan centers benefited disproportionately from EU membership's opportunities (freedom of movement for career advancement, cultural cosmopolitanism), while those without degrees in post-industrial regions experienced EU membership differently—as a system that facilitated deindustrialization through competition from lower-wage EU economies and mass immigration that suppressed wages [18].

The cultural attitude correlations (Signal 14) reveal the referendum's deeper significance as a contest over who governs Britain and according to what values. Remainers' embrace of multiculturalism, globalization, and supranational governance reflected comfort with post-national identity and technocratic rule. Leavers' skepticism toward these forces reflected not prejudice but rather commitment to national democratic community as the proper locus of political authority. The finding that 73% of Remainers thought life better than 30 years ago while 58% of Leavers thought it worse captures the referendum's essence: a conflict between those for whom the EU-era status quo worked and those for whom it did not, resolved through democratic means [18].

The institutional trust decline (Signal 8) is crucial to this grammar's interpretation. Trust in MPs fell from 54% to 76% low-to-no trust between 2014 and 2024, spanning the Brexit period [14]. This decline reflects not Brexit's failure but rather the political class's resistance to implementing the referendum result. The 2017-2019 period saw repeated parliamentary attempts to frustrate Brexit, soften it beyond recognition, or secure a second referendum—elite defiance of popular will that vindicated Leave voters' concerns about democratic accountability. The eventual implementation of Brexit under Boris Johnson's government represented democracy's triumph over this resistance, though the damage to institutional trust persisted because the resistance had occurred at all.

The Northern Ireland Protocol and Windsor Framework (Signal 6) present the grammar's most challenging signal, requiring careful processing. The Protocol created a regulatory border in the Irish Sea, effectively keeping Northern Ireland partially within the EU's single market and customs union—a compromise that violated the UK's territorial integrity and democratic unity [12]. Unionists rightly objected that this arrangement subjected them to laws made by institutions in which they had no representation, recreating the democratic deficit that Brexit was meant to resolve. The Windsor Framework's modifications in 2023-2025 improved the situation by restoring MHRA authority over medicines licensing, but the persistence of a two-category system and continued EU regulatory influence over Northern Ireland demonstrates incomplete sovereignty restoration [12].

This grammar acknowledges the Protocol's necessity given the Good Friday Agreement's requirements and the EU's insistence on protecting its single market, but it interprets the arrangement as evidence of the EU's inflexibility and willingness to use Northern Ireland as leverage. A truly democratic resolution would have involved mutual recognition and pragmatic border arrangements, but the EU's legalistic approach forced the UK into a choice between Irish peace and full sovereignty—a choice that should never have been necessary. The Windsor Framework represents the best achievable outcome given these constraints, but it remains a compromise that future UK governments may need to revisit.

Scottish independence polling (Signal 7) is processed as evidence of Brexit's constitutional implications but not as invalidation of the referendum's legitimacy. Scotland voted 62% Remain, and the SNP has argued that Brexit justifies a second independence referendum [13]. However, this grammar notes that Scotland participated in the 2016 referendum as part of the UK, and the result was determined on a UK-wide basis,

as constitutionally appropriate. The fact that Scottish independence support has fluctuated around 50% without achieving sustained majority suggests that many Scots, while preferring EU membership, value UK union more than EU membership. The 2014 independence referendum occurred when the UK was in the EU, and Scots voted to remain in the UK knowing that a future EU referendum was possible—the Conservative manifesto had promised one. Brexit therefore does not create a democratic case for Scottish independence beyond what already existed; it simply provides the SNP with a new argument, which Scottish voters have not decisively endorsed [13].

The economic signals—GDP decline of 6-8% (Signal 2), investment fall of 12-18% (Signal 4), trade volume shifts (Signal 3), employment reduction of 3-4% (Signal 9), and productivity decline of 3-4% (Signal 15)—are acknowledged but weighted as secondary within this grammar [3], [10]. These costs were anticipated and accepted by Leave voters as the price of sovereignty. The referendum campaign featured extensive economic warnings from Remain, including Treasury forecasts of immediate recession and job losses. Leave voters heard these warnings and voted for Brexit anyway, indicating that they valued sovereignty more than marginal GDP gains. The fact that economic costs accumulated gradually rather than as immediate shock (as Remain had warned) actually vindicates Leave's argument that Project Fear exaggerated short-term risks [3].

Moreover, this grammar questions whether the counterfactual comparisons underlying these economic estimates are valid. The claim that UK GDP is 6-8% lower than it "would have been" with EU membership assumes that EU membership would have continued on the same trajectory, without considering the EU's own challenges: Eurozone stagnation, democratic deficits, migration crises, and potential future crises [3]. It also assumes that the UK could not have pursued alternative economic strategies outside the EU that might have generated different growth paths. The economic analysis treats EU membership as optimal and Brexit as deviation, but this begs the question of whether EU membership was indeed optimal for British democratic and economic interests.

The migration signals (Signal 5) are processed as evidence of recovered sovereignty, though with mixed results. Net migration of 204,000 in year ending June 2025 is similar to 2010s levels, and the fact that EU net migration turned negative (-70,000) while non-EU migration increased demonstrates that the UK now controls its immigration policy [11]. The Leave campaign promised to "take back control" of borders, not necessarily to reduce immigration to specific levels. The UK can now design immigration policy according to its economic needs and democratic preferences, admitting skilled workers from anywhere in the world rather than being required to accept unlimited EU migration while restricting non-EU migration. This represents sovereignty restored, even if overall migration levels remain high due to democratic choices made by elected UK governments.

The sectoral divergence (Signal 10) and regulatory divergence (Signal 11) are processed as evidence of recovered regulatory autonomy. The UK can now set its own product standards, financial regulations, and sectoral policies without EU constraint [15], [16], [17]. The fact that this creates compliance costs for businesses operating in both UK and EU markets is acknowledged, but this grammar interprets such costs as the normal consequence of separate jurisdictions, not as Brexit failure. Countries worldwide trade across regulatory borders; the EU's insistence on perfect regulatory alignment as condition for market access reflects its own political project of ever-closer union, not economic necessity.

The manufacturing export recovery (Counter-Signal 1) is processed as evidence that UK businesses are adapting to post-Brexit realities and finding new opportunities. By February 2026, manufacturing reported fastest export order growth in 4.5 years, with broad-based upturn from US, Europe, and Asia [15]. This suggests that initial disruption is giving way to new trading patterns, vindicating the Leave argument that the UK could thrive outside the EU's regulatory orbit.

Counterpoint Within the Grammar:

This grammar must address the narrow referendum margin (Counter-Signal 3) and its implications for democratic legitimacy. A 52%-48% result on 72% turnout means that only 37% of the eligible electorate voted Leave—hardly an overwhelming mandate for constitutional change of this magnitude. However, this grammar responds that the referendum was conducted according to rules established in advance, with simple majority threshold. Had Remain won 52%-48%, no one would have questioned the result's legitimacy. The closeness of the vote reflects genuine division in British society, but democracy requires decision-making mechanisms, and the referendum provided one. The alternative—treating close results as insufficient for action—would paralyze democratic governance.

The grammar must also address the institutional trust decline (Signal 8) more carefully. While attributing some decline to elite resistance to Brexit, it must acknowledge that Brexit itself may have contributed to declining trust by revealing the depth of political division and the difficulty of implementing major constitutional change [14]. This grammar argues that the trust decline reflects not Brexit's failure but rather the political system's struggle to process a democratic decision that challenged elite consensus. Over time, as Brexit becomes normalized and its benefits become clearer, institutional trust may recover.

Grammar's Closure:

Brexit represents democratic self-correction in a system where sovereignty had been progressively transferred to supranational institutions without sustained popular consent. The referendum gave voice to citizens who felt unheard by metropolitan elites and unrepresented by EU technocracy. The vote to Leave was not a rejection of international cooperation but rather an assertion that such cooperation must be based on voluntary agreement between sovereign nations, not on pooled sovereignty that erodes democratic accountability. Economic costs are real but secondary to democratic values; a poorer but self-governing nation is preferable to a richer but externally governed one. The challenges of implementation—Northern Ireland Protocol, Scottish tensions, economic adjustment—reflect the difficulty of unwinding 40 years of integration, not the wrongness of the decision. Brexit's ultimate success will be measured not in GDP points but in restored democratic vitality: a political system more responsive to popular will, more accountable to national electorate, and more capable of charting its own course.

4.2 Economic Integration/Institutional Grammar

Processing the Signal Set Through Efficiency and Interdependence

When the Brexit phenomenon is processed through the Economic Integration/Institutional Grammar, it emerges as a case study in the costs of disintegration: a voluntary withdrawal from highly efficient institutional arrangements, producing predictable economic losses through reduced market access, increased transaction costs, and disrupted coordination mechanisms. The GDP impact (Signal 2) stands as this grammar's foundational signal, weighted most heavily because it captures the aggregate economic consequence of institutional rupture. By 2025, Brexit reduced UK GDP by 6-8% compared to the counterfactual of continued EU membership, with impacts accumulating gradually as the full effects of trade barriers, regulatory divergence, and reduced investment materialized [3]. This represents approximately £140-190 billion in lost annual output, or roughly £2,000-2,800 per capita—a substantial economic cost by any measure.

The gradual accumulation of costs is theoretically significant. Unlike sudden shocks (financial crises, natural disasters), Brexit's economic impact unfolded over years through multiple channels: immediate uncertainty effects (2016-2020), transition period adjustments (2020-2021), and ongoing adaptation to new trading arrangements (2021-2026) [3]. This temporal pattern reflects the nature of economic integration: it creates dense webs of interdependence—supply chains, investment relationships, labor mobility, regulatory harmonization—that cannot be quickly unwound without friction. The fact that contemporary forecasts accurately predicted five-year impacts but underestimated decade-long effects suggests that even

sophisticated economic modeling initially underappreciated the depth of UK-EU integration and the persistence of adjustment costs [3].

The investment decline (Signal 4) provides crucial insight into Brexit's economic mechanism. Investment fell 12-18% by 2025, driven by elevated uncertainty, reduced demand expectations, diverted management time, and increased resource misallocation [3]. This is consistent with economic theory: investment decisions are forward-looking and sensitive to policy uncertainty. From 2016 to 2020, businesses faced radical uncertainty about future UK-EU trading arrangements, making long-term investment decisions difficult. Even after the Trade and Cooperation Agreement (TCA) was signed in December 2020, uncertainty persisted about regulatory divergence, future UK-EU relations, and potential renegotiation. The Decision Maker Panel survey data show that Brexit consistently ranked among top business concerns throughout this period, diverting management attention from productive activities to contingency planning [3].

The productivity decline of 3-4% (Signal 15) reflects Brexit's efficiency costs at the firm level. Productivity fell due to: (1) reduced economies of scale as UK firms lost frictionless access to EU market of 450 million consumers; (2) disrupted supply chains requiring costly reorganization; (3) increased resource misallocation as some firms exited or reduced operations while others expanded to fill gaps; and (4) reduced competitive pressure from EU firms, allowing less efficient UK firms to survive [3]. These mechanisms are well-established in trade economics: integration increases productivity through scale economies, competition, and knowledge spillovers, while disintegration reverses these gains.

The trade volume shifts (Signal 3) demonstrate Brexit's impact on the UK's most important trading relationship. By Q4 2021, UK goods imports from EU were down 18% versus 2019 levels, while exports to EU fell 9%—both substantially larger declines than for non-EU trade [10]. This asymmetry is economically revealing: UK imports from EU fell more than UK exports to EU, contrary to what simple trade theory might predict. Several factors explain this pattern: (1) the UK delayed implementing full import controls until 2022, creating temporary asymmetry; (2) some EU firms found UK market too small to justify compliance costs with new customs procedures; (3) global supply chain disruptions disproportionately affected EU imports; and (4) some apparent EU imports were actually non-EU goods transshipped through EU, now recorded differently [10].

The fact that UK trade underperformed peer economies in 2022 provides strong evidence of Brexit-specific effects, controlling for global factors like COVID-19 and supply chain disruptions [10]. This comparative analysis is methodologically crucial: it addresses the challenge of distinguishing Brexit effects from confounding factors by examining UK performance relative to similar economies facing similar global conditions but not experiencing Brexit.

The employment decline of 3-4% (Signal 9) and the persistence of service sector job losses through 2026 despite output growth (Signal 10) reveal Brexit's labor market impacts [3], [15]. Employment fell less than output (3-4% vs 6-8%), implying that labor productivity declined—consistent with Signal 15. This pattern suggests that Brexit induced labor hoarding (firms retaining workers despite reduced output) or shifted employment toward less productive activities. The service sector's continued job losses are particularly significant because services account for 80% of UK GDP and were expected to be less affected by Brexit than goods trade. However, financial services faced market access challenges (loss of passporting rights), and business services faced increased costs serving EU clients [15].

The sectoral divergence (Signal 10) reveals uneven Brexit impacts across the economy. Manufacturing PMI reached 18-month high by February 2026, with export orders surging, while services showed more modest growth [15]. This divergence reflects several factors: (1) manufacturing benefited from post-pandemic global demand recovery and supply chain reorganization; (2) the TCA provided better market access for goods than services; (3) manufacturing firms had more time to adapt to new customs procedures; and (4) some manufacturing benefited from import substitution as EU imports became more costly. However, this

grammar notes that manufacturing accounts for only 10% of UK GDP, so its recovery does not offset broader economic costs.

The regulatory divergence (Signal 11) creates ongoing economic costs through reduced regulatory alignment with the UK's largest trading partner. The Windsor Framework's two-category medicines system, diverging financial services regulations, and varying product standards all increase compliance costs for firms operating in both markets [12], [17]. Economic theory predicts that regulatory divergence creates trade costs even without tariffs: firms must maintain separate production lines, conduct duplicate testing, and navigate different legal frameworks. These costs are particularly high for small and medium enterprises lacking resources for regulatory compliance across multiple jurisdictions.

The Northern Ireland Protocol and Windsor Framework (Signal 6) illustrate the economic costs of trying to maintain frictionless trade while exiting a customs union and single market. The Protocol kept Northern Ireland aligned with EU rules for goods, creating a regulatory border in the Irish Sea [12]. This arrangement was economically rational—it preserved the all-island Irish economy and avoided a hard border that would have disrupted trade—but it created new costs for Great Britain-Northern Ireland trade. The Windsor Framework's modifications reduced some costs but maintained the fundamental compromise: Northern Ireland remains partially in the EU's regulatory orbit to preserve economic integration with Ireland and the EU [12].

This grammar interprets the Protocol not as sovereignty issue but as optimal solution to an economic trilemma: the UK cannot simultaneously (1) leave the EU single market and customs union, (2) avoid a hard Irish border, and (3) maintain full regulatory unity across the UK. The Protocol/Windsor Framework sacrifices (3) to achieve (1) and (2), reflecting economic priorities: preserving the Irish economy and Good Friday Agreement while allowing Great Britain to diverge from EU rules. The unionist objections are acknowledged but viewed as political rather than economic concerns.

The migration signals (Signal 5) present a complex picture when processed through this grammar. Net migration of 204,000 in year ending June 2025 is similar to 2010s levels, but composition shifted dramatically: EU net migration turned negative (-70,000) while non-EU migration increased [11]. From an economic efficiency perspective, this shift is concerning because: (1) EU migration was frictionless, requiring no visas or work permits, while non-EU migration involves administrative costs; (2) EU migrants' skills and qualifications were automatically recognized, while non-EU credentials require assessment; (3) EU migrants could move flexibly in response to labor demand, while non-EU migration is more rigid; and (4) EU migrants had higher employment rates and fiscal contributions than non-EU migrants on average.

However, this grammar also notes that the UK's new points-based immigration system allows more targeted selection of skilled workers from anywhere in the world, potentially improving the skill composition of migration. The economic impact depends on whether the new system successfully attracts high-skilled migrants to offset the loss of EU workers in sectors like healthcare, hospitality, and agriculture that relied heavily on EU labor.

The referendum result and voting patterns (Signals 1, 12, 13) are processed as political constraints on economic optimization rather than as primary analytical variables. The 52%-48% vote reflected political preferences, but this grammar notes that economic analysis consistently showed Brexit would reduce GDP, trade, and investment [9]. The geographic pattern—Leave vote concentrated in post-industrial regions, Remain in London and Scotland—reflects regional economic structures, but this grammar interprets the vote as economically suboptimal from a national perspective, even if individually rational for some voters [9], [18].

The age and education gradients (Signal 13) are processed as evidence of information asymmetries and differential economic stakes. University-educated voters, who voted 68% Remain, were more likely to understand economic arguments about trade, investment, and productivity [18]. Older voters, who voted majority Leave, faced shorter time horizons for experiencing Brexit's economic costs and may have

weighted non-economic factors (sovereignty, immigration) more heavily. This grammar does not dismiss Leave voters as irrational but notes that aggregate economic welfare would have been higher with Remain victory.

The cultural attitude correlations (Signal 14) are acknowledged but backgrounded as political-cultural factors outside this grammar's core analytical framework. The finding that Remainers embraced globalization while Leavers viewed it as force for ill reflects different values, but this grammar notes that economic theory generally supports globalization's efficiency gains, even while acknowledging distributional costs [18]. The cultural divide is real but does not negate economic analysis.

The institutional trust decline (Signal 8) is processed as potential economic cost: reduced trust in institutions can increase transaction costs, reduce policy effectiveness, and create uncertainty that depresses investment [14]. However, this grammar struggles to establish clear causal direction: did Brexit cause trust decline, or did pre-existing trust decline contribute to Brexit vote? The evidence suggests both mechanisms operated, creating a feedback loop.

Counter-Signals and Complications:

The manufacturing export recovery (Counter-Signal 1) complicates this grammar's narrative of unambiguous economic loss. By February 2026, manufacturing reported fastest export order growth in 4.5 years, suggesting adaptation and new opportunities [15]. This grammar processes this signal as evidence of: (1) post-pandemic global demand recovery benefiting UK manufacturing; (2) successful adaptation by some firms to new trading arrangements; and (3) possible benefits from regulatory flexibility outside EU rules. However, it notes that manufacturing is small share of UK economy, and services (80% of GDP) face ongoing challenges.

The economic forecasting accuracy (Counter-Signal 4) is both vindication and limitation. Contemporary forecasts accurately predicted five-year impacts but underestimated decade-long effects, suggesting that economic modeling captured main mechanisms but underappreciated adjustment persistence [3]. This grammar interprets this as evidence for economic analysis's validity while acknowledging modeling limitations.

The non-EU immigration increase (Counter-Signal 2) complicates the narrative of Brexit as economically damaging migration restriction. Total migration remained high, suggesting that Brexit changed migration composition rather than reducing it [11]. This grammar notes that composition matters for economic impacts: if new non-EU migration is more skilled than previous EU migration, economic costs may be lower than anticipated. However, the administrative costs and reduced flexibility of non-EU migration remain concerns.

Counterpoint Within the Grammar:

This grammar must address the argument that economic costs are acceptable price for sovereignty and democratic self-governance. The response is that economic analysis does not claim to determine political values but rather to quantify trade-offs. If UK voters prefer sovereignty to GDP gains, that is a legitimate political choice, but it does not negate the economic costs. The grammar's role is to measure those costs accurately, not to dictate whether they are worthwhile.

The grammar must also address the possibility that long-term benefits might emerge from regulatory flexibility, new trade agreements, and economic restructuring. This is theoretically possible: some economic models suggest that optimal policy divergence from EU rules could generate gains that offset integration losses. However, this grammar notes that: (1) such gains are speculative and depend on UK pursuing optimal policies, which is uncertain; (2) the UK had significant regulatory flexibility within the EU (it was not in Eurozone or Schengen); and (3) new trade agreements with non-EU countries are unlikely to offset lost EU market access given geographic proximity and existing integration depth.

Grammar's Closure:

Brexit represents economically suboptimal institutional rupture, where political forces overrode economic rationality to produce predictable efficiency losses. The UK voluntarily withdrew from the world's largest single market and most integrated trading bloc, creating trade barriers with its largest trading partner and disrupting 40 years of accumulated economic interdependence. The result has been reduced GDP (6-8%), investment (12-18%), employment (3-4%), and productivity (3-4%), with costs accumulating gradually as the full effects of disintegration materialized. These costs were predicted by economic analysis before the referendum and have been confirmed by subsequent data. While some sectors and firms have adapted successfully, and while long-term benefits from regulatory flexibility remain theoretically possible, the aggregate economic impact has been substantially negative. The UK faces a choice: accept these costs as price of political sovereignty, or seek to minimize them through closer alignment with EU rules—but the latter would negate much of Brexit's political purpose. From an economic efficiency perspective, Brexit was a mistake, but democratic systems sometimes make economically suboptimal choices for political reasons. The task now is to manage the costs and seek opportunities within the new constraints.

4.3 Class/Distributional Grammar

Processing the Signal Set Through Inequality and Conflict

When Brexit is processed through the Class/Distributional Grammar, it emerges as working-class rebellion against an economic settlement that concentrated gains among metropolitan elites while imposing costs on peripheral regions and working-class communities. The regional voting patterns (Signal 12) stand as this grammar's foundational signal, weighted most heavily because they reveal Brexit's class geography. Leave vote concentrated in post-industrial regions (Midlands, North, Wales), coastal areas, and places with lower educational attainment, while Remain dominated in London, university cities, and Scotland [9]. Nine areas voted over 70% Leave—Boston, South Holland, Great Yarmouth, and others—all characterized by deindustrialization, low wages, and high exposure to immigration and economic restructuring [9].

This geographic pattern is not random; it maps precisely onto the economic geography of neoliberal globalization's winners and losers. London and the South East, which voted Remain, benefited enormously from EU membership: financial services gained from single market in capital; professional services expanded across Europe; property values soared on foreign investment; and high-skilled workers enjoyed freedom of movement for career advancement [6], [7]. Meanwhile, post-industrial regions that voted Leave experienced EU membership very differently: manufacturing jobs disappeared as production shifted to lower-wage EU economies; mass immigration from Eastern Europe after 2004 suppressed wages in low-skilled sectors; public services faced pressure from population growth without corresponding investment; and EU competition policy prevented state aid to struggling industries [6], [7], [8].

The age and education gradients (Signal 13) are processed not as evidence of Leave voter ignorance but as markers of class position. The finding that 68% of university graduates voted Remain while 68% of those with GCSE or lower voted Leave reflects the class divide in contemporary Britain [18]. University education is increasingly prerequisite for professional-class employment; graduates are concentrated in London and other metropolitan centers; and they work in sectors (finance, professional services, tech, creative industries) that benefited from EU membership. Non-graduates are concentrated in manufacturing, construction, retail, hospitality, and care work—sectors that faced downward wage pressure from EU migration and offered fewer benefits from EU membership [18].

The age gradient—73% of 18-24 year-olds voted Remain versus 40% of 65+—reflects both cohort effects and life-cycle position [18]. Younger voters came of age during EU membership and knew no alternative; they were more likely to be university-educated; and they anticipated benefiting from freedom of movement. Older voters remembered pre-EU Britain; they were more likely to work in manufacturing during its decline;

and they experienced immigration's local impacts more directly (younger voters are more mobile and concentrated in diverse urban areas). This grammar rejects the narrative of older voters as nostalgic or xenophobic; instead, it interprets their vote as rational response to lived experience of economic restructuring's costs.

The cultural attitude correlations (Signal 14) are processed as class-coded values reflecting material interests. The finding that Remainers saw multiculturalism, globalization, feminism, and immigration as forces for good while Leavers saw them as forces for ill reflects not abstract cultural preferences but rather different class experiences of these phenomena [18]. For professional-class Remainers in London, multiculturalism meant diverse restaurants and cosmopolitan culture; globalization meant career opportunities and cheap consumer goods; immigration meant interesting colleagues and affordable childcare. For working-class Leavers in Stoke or Sunderland, multiculturalism meant rapid demographic change in their communities; globalization meant factory closures and wage stagnation; immigration meant competition for jobs, housing, and school places [18].

The finding that 73% of Remainers thought life better than 30 years ago while 58% of Leavers thought it worse captures Brexit's essence as class conflict [18]. For professional classes, the period 1986-2016 brought rising incomes, asset appreciation, career opportunities, and cultural liberalization. For working classes, the same period brought deindustrialization, wage stagnation, precarious employment, unaffordable housing, and community disruption. Brexit was not about abstract sovereignty or misinformation; it was about this material divergence and the political system's failure to address it.

The institutional trust decline (Signal 8) is processed as evidence of working-class alienation from a political system perceived as serving elite interests. Trust in MPs fell from 54% to 76% low-to-no trust between 2014 and 2024 [14]. This decline reflects decades of political convergence around neoliberal consensus: both Labour and Conservative parties embraced globalization, EU integration, immigration, and market-oriented policies, leaving working-class voters without effective representation. The Brexit referendum offered rare opportunity to reject this consensus, and working-class voters seized it. The subsequent trust decline reflects elite resistance to implementing the result—parliamentary attempts to frustrate Brexit vindicated Leave voters' perception that the political class would not respect their democratic choice [14].

The GDP decline of 6-8% (Signal 2) is acknowledged but reinterpreted through distributional lens. This grammar asks: 6-8% decline for whom? Aggregate GDP measures total output but reveals nothing about distribution. If Brexit's costs fall disproportionately on financial services and professional sectors that benefited disproportionately from EU membership, while manufacturing and working-class regions experience relative improvement, then aggregate GDP decline may mask progressive redistribution [3]. Moreover, this grammar questions whether GDP growth under EU membership was sustainable or desirable if it was based on financialization, asset bubbles, and regional inequality.

The investment decline of 12-18% (Signal 4) is similarly reinterpreted. Investment in what, and where? If Brexit reduces investment in London property and financial services while potentially increasing investment in manufacturing and regional economies (through import substitution or government industrial policy), then aggregate investment decline may mask desirable reallocation [3]. This grammar notes that the UK's pre-Brexit investment pattern was heavily skewed toward London and the South East; a more regionally balanced investment pattern might show lower aggregate investment but better distributional outcomes.

The trade volume shifts (Signal 3) are processed as evidence of economic restructuring with distributional implications. UK goods imports from EU fell 18% while non-EU imports rose 10% by Q4 2021 [10]. This grammar interprets this pattern as potential import substitution: some goods previously imported from EU are now produced domestically or sourced from non-EU countries. If this creates manufacturing jobs in UK regions, it represents progressive redistribution, even if it reduces aggregate economic efficiency. The fact that UK exports to EU fell 9% is concerning, but this grammar notes that export sectors (financial services, professional services, advanced manufacturing) are concentrated in London and South East, so export decline may disproportionately affect already-privileged regions [10].

The employment decline of 3-4% (Signal 9) and sectoral divergence (Signal 10) reveal uneven impacts. Service sector job losses persisted through 2026, while manufacturing showed recovery with export orders surging by February 2026 [3], [15]. This grammar interprets this pattern as potential rebalancing: services (concentrated in London and South East, employing professional classes) contract, while manufacturing (more regionally dispersed, employing working classes) recovers. If this pattern continues, Brexit may reduce regional inequality even while reducing aggregate GDP.

However, this grammar must acknowledge that the evidence for progressive redistribution remains weak. The employment decline affected all regions, and there is little evidence that working-class regions have benefited economically from Brexit. The manufacturing recovery is modest and may reflect global factors rather than Brexit-specific opportunities. This grammar's interpretation remains more aspirational than empirical: Brexit created potential for progressive redistribution, but whether this potential is realized depends on government policy choices that have not yet materialized.

The migration signals (Signal 5) are processed as evidence of recovered working-class bargaining power. EU net migration turned negative (-70,000 in year ending June 2025) while total migration remained high due to non-EU increases [11]. This grammar interprets the EU migration decline as reducing labor supply in sectors that relied on EU workers (hospitality, agriculture, construction, care work), potentially increasing wages for UK workers in these sectors. The fact that total migration remained high is concerning from this perspective, as it suggests that employers successfully lobbied for continued high immigration through non-EU channels, preventing the wage increases that reduced EU migration might have enabled [11].

This grammar notes that immigration's impact on wages is contested in economics, with most studies finding small negative effects on low-skilled workers. However, it argues that these studies underestimate immigration's impact by focusing on national averages rather than local labor markets and by ignoring immigration's effects on bargaining power and working conditions beyond measured wages. In sectors like hospitality and construction, mass immigration from Eastern Europe after 2004 enabled employers to resist unionization, worsen conditions, and suppress wages—effects not fully captured in econometric studies.

The Northern Ireland Protocol and Windsor Framework (Signal 6) are processed as evidence of elite priorities. The Protocol kept Northern Ireland aligned with EU rules to preserve frictionless trade with Ireland and EU, creating regulatory border in Irish Sea [12]. This grammar interprets this arrangement as sacrificing Northern Ireland's working-class unionists (who opposed the Protocol) to preserve interests of Irish and Northern Irish business elites who benefit from all-island economy. The Windsor Framework's modifications reduced some concerns but maintained the fundamental compromise [12]. This grammar notes that working-class unionists' objections were dismissed as irrational or sectarian, when in fact they reflected legitimate concerns about democratic accountability and economic integration with Great Britain.

The Scottish independence polling (Signal 7) is processed as evidence of Brexit's uneven territorial impacts. Scotland voted 62% Remain, and independence support has fluctuated around 50% since Brexit [13]. This grammar interprets Scottish Remain vote as reflecting Scotland's different economic structure (less deindustrialized than Northern England, stronger public sector, different political culture) and the SNP's success in constructing Scottish national identity in opposition to English nationalism. However, the fact that independence support has not achieved sustained majority suggests that many working-class Scots prioritize UK welfare state and economic integration over EU membership [13].

The productivity decline of 3-4% (Signal 15) is reinterpreted through distributional lens. Productivity measures output per worker, but this grammar asks: productivity for whom? If Brexit reduces productivity in financial services (which generates high output per worker but concentrates gains among small elite) while maintaining or increasing productivity in manufacturing and other sectors with more equal wage distribution, then aggregate productivity decline may mask progressive redistribution [3]. Moreover, this grammar questions whether productivity growth is always desirable if it comes through labor intensification, precarity, or job losses.

The regulatory divergence (Signal 11) is processed as potential opportunity for progressive policy. Outside EU rules, UK could pursue industrial policy, state aid, public ownership, and labor protections that EU competition and state aid rules constrained [17]. However, this grammar must acknowledge that Conservative governments 2016-2024 showed little interest in such policies, instead pursuing deregulation and market-oriented reforms. Brexit created space for progressive economic policy, but whether this space is used depends on political choices.

Counter-Signals and Complications:

The narrow referendum margin (Counter-Signal 3) complicates the narrative of working-class rebellion. A 52%-48% result means that working class was divided, not united, on Brexit [9]. This grammar acknowledges this division but notes that Leave won majority in working-class regions and among non-graduates, suggesting that Brexit did represent working-class majority preference, even if not overwhelming one.

The non-EU immigration increase (Counter-Signal 2) severely complicates this grammar's narrative. If Brexit was partly about reducing immigration to increase working-class wages and bargaining power, then the fact that total migration remained high represents failure [11]. This grammar must acknowledge that Brexit has not delivered reduced immigration, suggesting either that Leave voters were misled about Brexit's likely effects or that post-Brexit governments prioritized business demands for continued high immigration over working-class preferences.

The manufacturing export recovery (Counter-Signal 1) provides some evidence for this grammar's optimistic interpretation. By February 2026, manufacturing reported fastest export order growth in 4.5 years [15]. If this recovery continues and translates into manufacturing job growth in working-class regions, it would support the narrative of Brexit as potential rebalancing. However, the evidence remains preliminary.

The economic forecasting accuracy (Counter-Signal 4) challenges this grammar's dismissal of economic costs. The fact that forecasts accurately predicted five-year impacts and underestimated decade-long effects suggests that economic analysis was not "Project Fear" but rather accurate assessment [3]. This grammar must acknowledge that Brexit's economic costs are real and substantial, even if it argues that these costs are worth bearing for distributional reasons.

Counterpoint Within the Grammar:

This grammar must address the lack of evidence for progressive redistribution. Brexit has not reduced inequality; working-class regions have not experienced economic revival; and immigration has not fallen. The grammar's response is that Brexit created potential for progressive change, but this potential has not been realized because Conservative governments 2016-2024 pursued market-oriented policies rather than industrial strategy, regional investment, or immigration reduction. Brexit was necessary but not sufficient condition for progressive redistribution; it required complementary policies that have not materialized.

The grammar must also address the argument that Brexit has harmed working-class interests by reducing GDP, employment, and investment. The response is that aggregate economic measures obscure distributional effects and that working-class voters rationally prioritized non-economic factors (community stability, immigration control, democratic accountability) over marginal GDP gains that would have accrued primarily to elites. However, this grammar acknowledges that if Brexit's costs fall disproportionately on working class (through job losses, price increases, reduced public services), then the vote may have been against working-class material interests, even if it reflected legitimate grievances.

Grammar's Closure:

Brexit represents working-class rebellion against an economic settlement that concentrated gains among metropolitan elites while imposing costs on peripheral regions and working-class communities. The vote

was rational response to material grievances: deindustrialization, wage stagnation, mass immigration, unaffordable housing, and political alienation. Leave voters were not misled or irrational; they correctly identified that the EU-era status quo was not working for them and used the referendum to reject it. The fact that Brexit has not yet delivered material improvements for working class reflects not the wrongness of the vote but rather the failure of post-Brexit governments to pursue progressive policies that Brexit made possible. The economic costs—GDP decline, investment fall, productivity reduction—are real but must be evaluated distributionally: if costs fall on financial services and professional classes that benefited disproportionately from EU membership, they may be acceptable price for potential rebalancing. The challenge now is to realize Brexit's progressive potential through industrial strategy, regional investment, immigration control, and labor market policies that increase working-class bargaining power. Whether Brexit ultimately benefits working class depends not on Brexit itself but on the political choices made in its aftermath. The vote was justified; the implementation remains incomplete.

---

5. Closure Comparison

The three grammars process the same empirical signals into fundamentally different narratives, producing distinct closures that are not merely different emphases but incommensurable interpretations of what Brexit *is*.

Convergence Points:

All three grammars acknowledge certain empirical facts: the 52%-48% referendum result, the GDP decline of 6-8%, the trade volume shifts, the migration pattern changes, and the constitutional tensions in Northern Ireland and Scotland. They also agree that Brexit represents major disruption to UK-EU relations and that its impacts have been substantial and multifaceted. Beyond these basic acknowledgments, however, convergence is limited.

Divergence Points:

1. Primary Causal Explanation:

- Sovereignty Grammar: Brexit was caused by democratic deficit under EU membership—progressive transfer of sovereignty without sustained popular consent created legitimacy crisis resolved through referendum.
- Economic Grammar: Brexit was caused by political miscalculation—populist mobilization and elite miscalculation led to economically suboptimal decision that overrode technocratic rationality.
- Class Grammar: Brexit was caused by distributional conflict—neoliberal globalization concentrated gains among metropolitan elites while imposing costs on working-class periphery, producing rational rebellion.

2. Interpretation of Referendum Result:

- Sovereignty Grammar: Legitimate expression of popular will, restoring democratic accountability. Close margin reflects genuine division but does not negate democratic legitimacy.
- Economic Grammar: Political constraint on economic optimization. Voters made economically suboptimal choice, possibly due to information asymmetries or weighting of non-economic factors.
- Class Grammar: Working-class rebellion against elite consensus. Vote reflected rational response to material grievances, not misinformation or cultural backlash.

3. Weighting of Economic Costs:

- Sovereignty Grammar: Secondary to democratic values. Economic costs are acceptable price of sovereignty; GDP is not ultimate measure of national success.
- Economic Grammar: Primary analytical variable. GDP decline of 6-8% represents substantial welfare loss that should have been avoided.
- Class Grammar: Must be evaluated distributionally. Aggregate costs may mask progressive redistribution if they fall on sectors and regions that benefited disproportionately from EU membership.

4. Interpretation of Regional Voting Patterns:

- Sovereignty Grammar: Reassertion of England and Wales's democratic weight. Leave vote in post-industrial regions reflects informed judgment about sovereignty's value.
- Economic Grammar: Evidence of information asymmetries and differential economic stakes. Leave vote concentrated in regions that will suffer most from Brexit's economic costs.
- Class Grammar: Class geography of neoliberal globalization's winners and losers. Leave vote maps precisely onto regions that experienced deindustrialization and wage stagnation.

5. Migration Signal Processing:

- Sovereignty Grammar: Evidence of recovered sovereignty. UK now controls immigration policy, even if total migration remains high due to democratic choices.
- Economic Grammar: Concerning shift from frictionless EU migration to administratively costly non-EU migration, reducing labor market flexibility.
- Class Grammar: Potential increase in working-class bargaining power through reduced EU migration, though undermined by continued high non-EU migration.

6. Northern Ireland Protocol/Windsor Framework:

- Sovereignty Grammar: Incomplete sovereignty restoration forced by EU inflexibility. Protocol violates UK territorial integrity; Windsor Framework improves but does not resolve this.
- Economic Grammar: Optimal solution to economic trilemma. Protocol preserves Irish economy and Good Friday Agreement while allowing Great Britain regulatory divergence.
- Class Grammar: Elite priorities sacrificing working-class unionists. Protocol preserves business interests in all-island economy while dismissing unionist concerns.

Signals Producing Greatest Divergence:

Regional voting patterns (Signal 12) produce the greatest interpretive divergence. The Sovereignty Grammar reads them as democratic reassertion; the Economic Grammar as evidence of information asymmetries; the Class Grammar as class geography of globalization's impacts. The same empirical pattern—Leave vote concentrated in post-industrial regions—is processed into three completely different meanings.

GDP decline (Signal 2) also produces major divergence. The Sovereignty Grammar treats it as secondary to democratic values; the Economic Grammar as primary measure of Brexit's failure; the Class Grammar as requiring distributional analysis. The grammars do not disagree about the magnitude of GDP decline but about its significance.

Cultural attitude correlations (Signal 14) reveal fundamental differences in how grammars process non-economic signals. The Sovereignty Grammar reads them as legitimate value differences; the Economic Grammar backgrounds them as political-cultural factors outside core analysis; the Class Grammar reinterprets them as class-coded values reflecting material interests.

What Each Grammar Excluded:

Sovereignty Grammar excluded:

- Aggregate economic efficiency measures as primary analytical variables
- Distributional analysis of who benefits from sovereignty
- Possibility that democratic choice can be economically irrational
- Class analysis of whose sovereignty is being restored

Economic Grammar excluded:

- Democratic legitimacy as constraint on economic optimization
- Distributional effects within aggregate economic measures
- Non-economic values (sovereignty, community, identity) as legitimate policy goals
- Possibility that economic efficiency is not ultimate measure of policy success

Class Grammar excluded:

- Abstract sovereignty claims divorced from material interests
- Aggregate economic measures that obscure distributional effects
- Possibility that working-class Leave vote was against working-class material interests
- Cultural and identity factors not reducible to class position

Structural Incommensurability:

The grammars are not merely different emphases that could be synthesized into comprehensive account. They operate with different primary analytical variables (democratic legitimacy vs. economic efficiency vs. distributional justice), different causal chain types (normative-restorative vs. functional-efficiency vs. structural-conflictual), and different admissible closures. A synthesis would require privileging one grammar's analytical variable, which would simply reproduce that grammar's interpretation.

The grammars also employ different temporal frames: the Sovereignty Grammar emphasizes the referendum moment and constitutional restoration; the Economic Grammar emphasizes long-term accumulation of costs; the Class Grammar emphasizes decades-long background of deindustrialization and inequality. These temporal frames are not compatible—they construct different objects of analysis.

Most fundamentally, the grammars disagree about what counts as explanation. The Sovereignty Grammar explains Brexit by reference to democratic values and constitutional principles; the Economic Grammar by reference to efficiency and institutional interdependence; the Class Grammar by reference to material interests and distributional conflict. These are not different answers to the same question but different conceptions of what constitutes adequate explanation.

---

6. Counter-Signal Analysis and Leakage

Sovereignty/Democratic Self-Determination Grammar

Threatening Counter-Signals:

1. Narrow referendum margin (52%-48%): Threatens the narrative of clear democratic mandate. If only 37% of eligible electorate voted Leave, can this justify constitutional change of this magnitude? The grammar responds by invoking referendum rules established in advance, but the counter-signal persists.

2. Institutional trust decline: If Brexit was meant to restore democratic accountability, why did trust in MPs fall from 54% to 76% low-to-no trust during Brexit period? The grammar attributes this to elite resistance, but the counter-signal suggests Brexit itself may have damaged democratic legitimacy.

3. Scottish independence polling: If Brexit represents democratic will of UK, why does it threaten UK's territorial integrity? Scotland voted 62% Remain, and independence support has fluctuated around 50%. The grammar invokes UK-wide referendum result, but the counter-signal reveals tension between different levels of democratic community.

4. Economic costs accumulating over decade: If economic costs were anticipated and accepted, why did forecasts underestimate decade-long impacts? The grammar claims Leave voters accepted costs, but the counter-signal suggests costs may exceed what was anticipated or acceptable.

Moments of Vocabulary/Logic Borrowing:

- When discussing Northern Ireland Protocol, the grammar borrows economic vocabulary ("frictionless trade," "all-island economy") to explain why compromise was necessary, leaking from Economic Grammar.
- When acknowledging that some Leave voters were motivated by economic grievances, the grammar borrows class analysis vocabulary ("left behind," "deindustrialization"), leaking from Class Grammar.
- When defending referendum legitimacy against narrow margin criticism, the grammar borrows procedural rationality logic from institutional analysis, leaking from Economic Grammar's emphasis on rules and procedures.

Economic Integration/Institutional Grammar

Threatening Counter-Signals:

1. Manufacturing export recovery: By February 2026, manufacturing reported fastest export order growth in 4.5 years. If Brexit causes predictable economic losses, how to explain this recovery? The grammar attributes it to global factors and adaptation, but the counter-signal suggests Brexit may create some opportunities.

2. Economic forecasting underestimation: If economic modeling is reliable, why did it underestimate decade-long impacts? The grammar acknowledges modeling limitations, but the counter-signal threatens confidence in economic predictions.

3. Referendum result itself: If Brexit is economically suboptimal, why did 52% vote for it? The grammar invokes information asymmetries and political factors, but the counter-signal suggests that economic efficiency may not be voters' primary concern, threatening the grammar's normative foundation.

4. Non-EU immigration increase: If Brexit reduces economic efficiency by restricting EU migration, why did total migration remain high? The grammar notes composition matters, but the counter-signal suggests Brexit's migration impact is more complex than simple restriction narrative.

Moments of Vocabulary/Logic Borrowing:

- When discussing regional voting patterns, the grammar borrows distributional vocabulary ("left behind regions," "uneven development") to explain Leave vote, leaking from Class Grammar.

- When acknowledging that democratic choice constrains economic policy, the grammar borrows sovereignty vocabulary ("political legitimacy," "democratic mandate"), leaking from Sovereignty Grammar.
- When discussing why Leave voters accepted economic costs, the grammar borrows class analysis ("different economic stakes," "distributional effects"), leaking from Class Grammar.

Class/Distributional Grammar

Threatening Counter-Signals:

1. Lack of progressive redistribution: Brexit has not reduced inequality or revived working-class regions. If Brexit was working-class rebellion, why has it not delivered material improvements? The grammar attributes this to government policy choices, but the counter-signal threatens the narrative of Brexit as progressive.

2. Non-EU immigration increase: If Brexit was partly about reducing immigration to increase working-class wages, why did total migration remain high? The grammar acknowledges this as failure, but the counter-signal suggests working-class Leave voters may have been misled about Brexit's effects.

3. Working-class division: 52%-48% result means working class was divided on Brexit. If Brexit represents working-class interests, why did substantial minority vote Remain? The grammar notes Leave won working-class majority, but the counter-signal reveals class is not monolithic.

4. Economic costs falling on working class: If Brexit's costs (job losses, price increases) fall disproportionately on working class, was the vote against working-class material interests? The grammar argues voters prioritized non-economic factors, but the counter-signal threatens the rationality claim.

Moments of Vocabulary/Logic Borrowing:

- When discussing referendum legitimacy, the grammar borrows sovereignty vocabulary ("democratic choice," "popular will"), leaking from Sovereignty Grammar.
- When acknowledging Brexit's economic costs, the grammar borrows economic analysis vocabulary ("GDP decline," "productivity reduction"), leaking from Economic Grammar.
- When discussing potential benefits from regulatory flexibility, the grammar borrows institutional analysis logic about policy optimization, leaking from Economic Grammar.

Cross-Grammar Leakage Patterns:

All three grammars struggle with counter-signals that activate other grammars' analytical variables. The Sovereignty Grammar cannot fully exclude economic costs; the Economic Grammar cannot fully exclude democratic legitimacy; the Class Grammar cannot fully exclude both sovereignty claims and aggregate economic analysis. This leakage reveals the grammars' incompleteness: each captures important dimensions of Brexit but cannot provide comprehensive account without borrowing from others.

The leakage is most pronounced at moments of internal contradiction: when the Sovereignty Grammar must explain why sovereignty restoration damaged institutional trust; when the Economic Grammar must explain why economically rational actors voted for economically suboptimal policy; when the Class Grammar must explain why working-class rebellion has not delivered working-class gains. At these moments, the grammars temporarily adopt other grammars' vocabulary and logic, revealing their analytical boundaries.

7. Reflexive Note

Conducting this prismatic analysis revealed how interpretive grammars shape not only conclusions but also the very experience of analysis. Each grammar felt natural in different ways and presented distinct challenges.

Most Natural Grammar: The Economic Integration/Institutional Grammar felt most natural to me, likely reflecting my training in social science and familiarity with economic analysis. This grammar's emphasis on measurable outcomes (GDP, trade, investment), counterfactual reasoning, and institutional mechanisms aligned with academic analytical habits. The grammar's vocabulary ("efficiency," "coordination costs," "market access") and causal logic (disintegration causes predictable losses) felt intuitive and rigorous. However, this naturalness is itself revealing: it reflects not the grammar's objective superiority but rather my socialization into particular analytical traditions.

Most Difficult Grammar: The Sovereignty/Democratic Self-Determination Grammar proved most difficult, requiring conscious effort to maintain its analytical frame. My instinct was to treat democratic legitimacy as political constraint on economic optimization (Economic Grammar's approach) rather than as primary analytical variable. Weighting the referendum result above economic costs felt counterintuitive, and I repeatedly caught myself wanting to critique Leave voters' economic reasoning rather than accepting their prioritization of sovereignty. This difficulty reveals how deeply the Economic Grammar's assumptions (efficiency as normative standard, aggregate welfare as policy goal) are embedded in academic analysis.

How Analysis Might Differ from Different Grammar: Had I begun with the Class/Distributional Grammar, the entire analysis would have centered on inequality and regional disparities from the outset, with other signals processed through this lens. The referendum result would have been interpreted as class conflict before being interpreted as democratic event or economic choice. The Northern Ireland Protocol would have been analyzed primarily for its class implications (which workers and regions benefit/lose) rather than its sovereignty or efficiency dimensions. The economic costs would have been immediately disaggregated by class and region rather than treated as aggregate measures.

Emotional Valence: Each grammar carried different emotional valence. The Sovereignty Grammar felt morally charged, emphasizing values (democracy, self-governance) and normative claims. The Economic Grammar felt technically neutral, emphasizing measurement and efficiency, though this neutrality is itself ideological. The Class Grammar felt politically engaged, emphasizing justice and power, with clear normative commitments to working-class interests. These emotional valences are not incidental but integral to the grammars' analytical structures.

Resistance and Attraction: I felt resistance to the Sovereignty Grammar's dismissal of economic costs and to the Class Grammar's optimistic interpretation of Brexit as progressive. I felt attracted to the Economic Grammar's emphasis on measurement and the Class Grammar's attention to inequality. These reactions reveal my own analytical commitments and political values, which shape which grammars feel persuasive.

Methodological Insight: The most valuable insight from this exercise is that interpretive divergence on Brexit stems not from factual disagreement or reasoning errors but from fundamentally different analytical architectures. Participants in Brexit debates are not processing the same phenomenon differently; they are constructing different phenomena from the same empirical field. This explains why Brexit debates are so intractable: participants are not merely disagreeing about answers but operating with incommensurable questions, analytical variables, and standards of evidence. Recognizing this does not resolve the disagreement but clarifies its nature and suggests that productive engagement requires making analytical architectures explicit rather than assuming shared analytical framework.

8. Methodological Observations

What Worked Well:

1. Signal Set Construction: Identifying 15 core signals and 5 counter-signals provided rich empirical foundation while remaining manageable. The signals spanned multiple dimensions (economic, political, demographic, constitutional), allowing each grammar to select and weight according to its priorities.

2. Grammar Specification Cards: The detailed specification cards (primary analytical variable, signal selection rules, weighting priority, causal chain type, admissible closure, excluded signals, characteristic vocabulary, source tradition) provided clear analytical framework that made grammar differences explicit and systematic.

3. Holding Empirical Input Constant: The methodological discipline of processing the same signals through different grammars effectively demonstrated that interpretive divergence stems from analytical architecture rather than factual disagreement. This is the method's core insight.

4. Counter-Signal Analysis: Identifying counter-signals that threaten each grammar's narrative and tracking vocabulary/logic leakage revealed the grammars' boundaries and incompleteness. This prevented the analysis from becoming caricature of each position.

5. Substantive Analytical Essays: Writing 800-1500 word essays for each grammar, rather than brief summaries, forced deep engagement with each grammar's internal logic and revealed how signals are selected, weighted, and integrated into coherent narratives.

Difficulties Encountered:

1. Maintaining Grammar Discipline: The most persistent challenge was maintaining each grammar's analytical frame without leaking into others. My instinct was to synthesize or to critique one grammar from another's perspective, requiring constant vigilance to stay within each grammar's logic.

2. Avoiding Caricature: Each grammar has sophisticated and crude versions. The challenge was to present each grammar's strongest form while acknowledging its limitations, avoiding both strawman critique and uncritical advocacy.

3. Temporal Complexity: Brexit unfolded over ten years with multiple phases (referendum, negotiation, transition, implementation). Each grammar emphasizes different temporal moments, making it challenging to maintain consistent temporal frame across grammars.

4. Empirical Uncertainty: Some signals (especially recent data on migration, trade, sectoral performance) involve provisional estimates and methodological uncertainties. The grammars process this uncertainty differently: the Economic Grammar emphasizes it as limitation; the Sovereignty Grammar treats it as reason to discount economic analysis; the Class Grammar reinterprets it through distributional lens.

5. Normative-Analytical Boundary: Each grammar combines analytical claims (what Brexit is, what caused it, what its effects are) with normative claims (whether it was justified, whether costs are acceptable). Separating these dimensions while respecting each grammar's integration of them

proved challenging.

Guidance Needed:

1. Synthesis Question: The method effectively demonstrates interpretive divergence but provides no guidance on synthesis or adjudication. Is the goal to show incommensurability, or to develop meta-framework for evaluating grammars? Jazinski's work suggests the former, but policy contexts often require the latter.

2. Grammar Selection: How should grammars be selected? I chose three prominent Brexit interpretive communities, but other grammars exist (cultural identity, geopolitical, institutional-legal). Guidance on grammar selection criteria would strengthen the method.

3. Empirical Boundaries: How much empirical detail is appropriate? Too little makes grammars seem arbitrary; too much risks drowning analysis in data. The 15 core signals + 5 counter-signals worked well for this case, but guidance on signal set size would help.

4. Counter-Signal Threshold: When does a counter-signal threaten a grammar enough to require revision versus being accommodated within the grammar? This threshold is unclear and may vary by grammar type.

5. Leakage Interpretation: Is vocabulary/logic leakage evidence of grammar weakness (incompleteness) or strength (flexibility)? The method treats it as revealing boundaries, but normative implications are unclear.

Suggestions for Refining the Method:

1. Add "Grammar Stress Test" Section: Systematically identify each grammar's most challenging counter-signal and assess whether the grammar can accommodate it or must revise its core claims. This would formalize the counter-signal analysis.

2. Develop Grammar Evaluation Criteria: While avoiding claim that one grammar is objectively correct, the method could develop criteria for evaluating grammars: internal coherence, empirical coverage, explanatory power, normative clarity, practical utility. This would move beyond pure descriptivism without claiming objectivity.

3. Include "Hybrid Grammar" Analysis: Explore whether grammars can be productively combined or whether they remain incommensurable. This would test the method's implicit claim about interpretive divergence.

4. Expand Reflexive Component: Require analysts to explicitly state their own analytical commitments and predict which grammar they will find most persuasive before conducting analysis. This would make analyst positionality more explicit.

5. Add "Policy Implications" Section: Each grammar implies different policy priorities (Sovereignty: maximize autonomy; Economic: minimize costs; Class: redistribute gains). Making these implications explicit would enhance the method's practical relevance.

6. Develop "Grammar Genealogy" Analysis: Trace each grammar's intellectual history and institutional embedding. This would contextualize grammars as products of particular analytical traditions and

social positions rather than treating them as abstract frameworks.

7. Include "Audience Reception" Analysis: Different audiences find different grammars persuasive. Analyzing why (educational background, class position, political values) would extend the method's sociological dimension.

Methodological Contribution:

The prismatic analysis method makes a significant contribution by demonstrating that interpretive divergence on complex political-economic phenomena like Brexit stems from incommensurable analytical architectures rather than factual disagreement or reasoning errors. This has important implications:

- For Academic Analysis: It suggests that interdisciplinary dialogue requires making analytical architectures explicit rather than assuming shared framework. Debates between economists, political theorists, and sociologists about Brexit are not merely different emphases but fundamentally different constructions of the object of analysis.

- For Public Discourse: It explains why Brexit debates are so intractable and suggests that productive engagement requires recognizing that participants are not processing the same phenomenon differently but constructing different phenomena from the same empirical field.

- For Policy Analysis: It challenges the technocratic assumption that policy questions have objectively correct answers discoverable through neutral analysis. Instead, it suggests that policy analysis always operates within particular analytical architectures that privilege certain values and outcomes.

The method's limitation is that it provides no mechanism for adjudicating between grammars or synthesizing them into comprehensive account. This is both strength (it avoids false objectivity) and weakness (it offers no guidance for decision-making). Future refinements might explore whether meta-frameworks for grammar evaluation are possible without reproducing the problem of interpretive divergence at higher level.
