Prismatic Analysis: Social Media Regulation (2016–2026)

A Jazinski Method Investigation

Analysis Date: March 12, 2026
Temporal Scope: 2016–2026
Domain: Social Media Regulation
Evidence Base: 297 scholarly sources (top 30 analyzed)

Step 0: Reflexive Declaration

Analyst Position: This analysis is conducted from the position of a research observer examining regulatory discourse through academic literature published between 2016 and 2026. The analyst acknowledges three inherent biases that shape this investigation:

First, the evidence base privileges European regulatory developments, particularly the Digital Services Act (DSA), which dominates recent scholarship. This creates a geographic skew where EU frameworks appear more "advanced" or "comprehensive" than they may be in practice, while U.S. Section 230 debates receive less granular empirical attention despite their foundational importance.

Second, the temporal position of March 2026 means we observe the DSA during its early implementation phase (2023–2026), a period characterized by compliance reporting, database establishment, and initial audits. This creates a methodological tension: we analyze a regulatory regime still crystallizing, where early

signals may not represent stable patterns. The analysis risks mistaking implementation artifacts for structural features.

Third, the analyst operates within academic discourse that has normalized certain regulatory assumptions—that transparency is inherently beneficial, that algorithmic accountability is achievable through audits, that platform power requires state intervention. These assumptions structure what counts as a "signal" versus "noise" in the observation field. The Jazinski method's requirement to identify counter-signals and contested signals is designed to mitigate this bias, but cannot eliminate the analyst's embeddedness in these discursive formations.

Methodological Commitment: This analysis commits to treating regulatory grammars not as normative frameworks to be evaluated for "correctness," but as distinct sense-making systems that organize evidence differently. The goal is not to determine which grammar is "right," but to understand how each grammar processes the same signals into different regulatory realities. Counter-signals are not "problems to be solved" but constitutive elements that reveal the limits and tensions within each grammar.

Temporal Caveat: Writing in March 2026, this analysis captures a regulatory moment characterized by institutional experimentation, contested implementation, and incomplete data. Future observers may find that signals identified here as "primary" were transient, while counter-signals dismissed by contemporary actors proved structurally significant. This reflexive declaration serves as a timestamp, marking the analyst's position within the very regulatory transformation being analyzed.

Section 1: Observation Field

1.1 Temporal Boundaries and Regulatory Epochs

The decade 2016–2026 encompasses three distinct regulatory epochs in social media governance:

Epoch 1: Crisis Recognition (2016–2019)
This period begins with the 2016 U.S. presidential election and the Cambridge Analytica scandal (2018), which transformed social media from a communication technology into a governance crisis. The observation field during this epoch is characterized by reactive policy formation, platform self-regulation promises, and the emergence of "techlash" discourse. Key regulatory signals include the EU's General Data Protection Regulation (GDPR, 2018), early content moderation controversies, and the first systematic studies of algorithmic amplification [30].

Epoch 2: Regulatory Formulation (2019–2023)
This epoch witnesses the translation of crisis recognition into formal regulatory architecture. The EU develops the Digital Services Act (proposed 2020, adopted 2022, enforced 2023), while U.S. debates intensify around Section 230 reform without producing federal legislation [3]. Platform transparency reports become standardized, academic research on algorithmic harms proliferates, and the concept of "platform constitutionalism" enters legal scholarship [17]. This period establishes the regulatory grammars that structure subsequent implementation.

Epoch 3: Implementation and Contestation (2023–2026)
The current epoch, in which this analysis is conducted, is defined by the operationalization of the DSA's transparency database (launched September 2023), the production of compliance data, and the emergence of empirical evidence about regulatory effectiveness. This period reveals the gap between regulatory design and implementation reality, as platforms navigate compliance requirements while researchers audit self-reported data [2], [5], [15], [16], [23], [27].

1.2 Geographic Scope and Jurisdictional Dynamics

The observation field is structured by a fundamental geographic asymmetry: European regulatory assertiveness versus American regulatory stasis. The EU's DSA represents the most comprehensive attempt to regulate platform governance through transparency mandates, algorithmic accountability requirements, and procedural rights frameworks [1], [4], [8], [11], [14], [17], [21]. In contrast, U.S. regulation remains fragmented, with Section 230 debates producing political polarization but no federal reform, while state-level initiatives create jurisdictional complexity [3].

This geographic asymmetry shapes the evidence base itself. Of the top 30 papers analyzed, 26 focus primarily on EU regulation, particularly the DSA, while only 4 substantively engage with U.S. regulatory developments. This is not merely a sampling artifact but reflects the reality that the EU has produced more regulatory infrastructure to study. However, this creates an observational bias: the analysis may overweight European regulatory logics while underrepresenting alternative approaches.

1.3 Institutional Actors and Power Geometries

The observation field contains multiple actor categories, each generating distinct types of signals:

Platforms as Regulated Entities: Eight major platforms—TikTok, X (formerly Twitter), Meta (Facebook/Instagram), YouTube, Snapchat, LinkedIn, Pinterest, and others—submit moderation data to the DSA Transparency Database. Their compliance behaviors, reporting inconsistencies, and strategic responses to regulation constitute primary empirical signals [2], [10], [15], [16], [27].

Regulatory Authorities: The European Commission, national Digital Services Coordinators, and emerging audit bodies implement and enforce the DSA. Their enforcement actions, guidance documents, and institutional capacity constraints shape regulatory effectiveness [12], [13].

Academic Auditors: Researchers analyzing the DSA Transparency Database, conducting algorithmic audits, and evaluating platform compliance constitute a quasi-regulatory layer. Their findings reveal implementation gaps and data quality issues that regulatory authorities may lack capacity to detect [2], [5], [15], [16], [23], [27].

Civil Society and Advocacy Groups: Organizations focused on digital rights, content moderation fairness, and platform accountability generate normative pressure and participate in regulatory processes, though their influence varies across jurisdictions [11], [30].

1.4 Evidentiary Landscape and Data Infrastructures

The observation field is structured by new data infrastructures that make platform behavior visible in unprecedented ways:

DSA Transparency Database: Launched September 2023, this database contains over 353 million moderation records from the first 100 days, representing the most comprehensive dataset on content moderation ever assembled [2]. However, the database's structure, data quality issues, and platform reporting inconsistencies mean it is simultaneously a breakthrough in transparency and a contested evidentiary artifact [2], [5], [10], [15], [16], [23], [27].

Platform Transparency Reports: Voluntary reports published by platforms since the mid-2010s, now supplemented by DSA-mandated reporting. These reports reveal moderation volumes, appeal rates, and automation levels, but cross-checking reveals significant inconsistencies between self-reported data and database submissions [2], [30].

Algorithmic Audit Studies: Academic research employing computational methods to test platform algorithms for bias, amplification patterns, and recommendation dynamics. These studies face methodological challenges due to platform opacity and API restrictions [19], [22], [29].

1.5 Thematic Domains and Regulatory Targets

The observation field encompasses multiple overlapping regulatory concerns:

Content Moderation Governance: Rules, processes, and technologies for removing or restricting harmful content, including hate speech, disinformation, violent extremism, and child sexual abuse material. This domain generates the most empirical signals, as moderation actions are now systematically reported [2], [6], [11], [15], [16], [20], [28], [30].

Algorithmic Transparency and Accountability: Requirements for platforms to explain, audit, and potentially modify recommendation algorithms, ranking systems, and automated decision-making processes [1], [5], [19], [22], [23], [29].

Platform Market Structure: Concerns about concentration, competition, interoperability, and the economic power of dominant platforms. This domain receives less attention in the DSA-focused literature but represents a distinct regulatory grammar [7], [26].

User Rights and Due Process: Procedural protections for users subject to content moderation, including notice, explanation, appeal mechanisms, and external review [11], [30].

1.6 Methodological Constraints and Observational Limits

The observation field is bounded by several methodological constraints that shape what can be known:

Temporal Lag: The DSA's enforcement began in August 2023 for Very Large Online Platforms (VLOPs). As of March 2026, we observe only 30 months of implementation—insufficient time to assess long-term effects, adaptation dynamics, or unintended consequences.

Platform Opacity: Despite transparency mandates, platforms retain control over what data they report, how they categorize moderation actions, and what algorithmic details they disclose. Academic auditors consistently identify inconsistencies, missing data, and reporting artifacts that limit observational validity [2], [5], [10], [15], [16].

Jurisdictional Boundaries: The DSA applies only to EU users, creating a fragmented regulatory reality where platforms operate under different rules in different jurisdictions. Observational studies typically cannot distinguish EU-specific effects from global platform changes.

Counterfactual Absence: We lack robust counterfactuals for what platform behavior would look like without regulation, making causal attribution difficult. Observed changes may reflect broader industry trends, public pressure, or strategic platform decisions rather than regulatory compliance.

1.7 Discursive Formations and Conceptual Vocabularies

The observation field is structured by evolving conceptual vocabularies that shape how regulatory problems are named and understood:

From "Intermediary Liability" to "Platform Governance": The shift from legal immunity frameworks (Section 230, e-Commerce Directive) to comprehensive governance regimes (DSA) represents a fundamental reconceptualization of platforms from neutral intermediaries to active governors of digital public spheres [3], [4], [8], [26].

From "Content Moderation" to "Systemic Risk Management": The DSA introduces the concept of "systemic risks" that platforms must assess and mitigate, expanding regulatory focus beyond individual content decisions to platform design, algorithmic amplification, and societal-level effects [12], [13], [21].

From "Transparency" to "Automated Transparency": The evolution from voluntary transparency reports to mandated, structured, machine-readable data submissions represents a shift toward "automated transparency" that enables computational auditing but also creates new forms of opacity [5], [23].

These conceptual shifts are not merely semantic but constitute different ways of organizing the observation field, determining what counts as evidence, and structuring regulatory intervention.

Section 2: Signal Compilation

2.1 Primary Signals (15)

Signal 1: DSA Transparency Database Volume
The DSA Transparency Database collected 353.12 million moderation records from eight social media platforms within its first 100 days of operation (September–December 2023), representing an unprecedented scale of content moderation visibility [2]. This volume signal indicates both the massive scale of platform moderation and the regulatory capacity to mandate systematic reporting.

Signal 2: Platform Reporting Inconsistencies
Cross-checking DSA database submissions against platforms' own transparency reports reveals substantial inconsistencies. X (formerly Twitter) exhibits the most severe discrepancies, with 99.8% of its Statements of Reasons (SoRs) targeting synthetic media—a figure inconsistent with its transparency report and suggesting either reporting errors or strategic compliance [2]. This signal reveals the gap between regulatory mandates and implementation reality.

Signal 3: Automation Dominance in Moderation
TikTok reports that 92% of its moderation actions employ fully automated means, while other platforms show varying automation levels [2]. This signal indicates the centrality of algorithmic decision-making in content governance and raises questions about procedural rights when human review is minimal.

Signal 4: Moderation Delay Patterns
Pinterest exhibits high delays in applying moderation decisions, with 7% of actions taking over 24 hours [2]. This temporal signal suggests resource constraints, prioritization strategies, or technical limitations that affect the timeliness of content governance.

Signal 5: Language Disparities in Moderation Workforce
Analysis of moderation workforce allocation reveals systematic language disparities, with minority language communities receiving disproportionately less human moderation capacity [25]. This signal indicates structural inequalities in how platform governance resources are distributed globally.

Signal 6: DSA Database Structural Inadequacy
Researchers identify that the DSA database structure is "partially inadequate for the platforms' reporting needs," with platforms adhering "only in part to the philosophy and structure of the database" [2]. This signal reveals a mismatch between regulatory design and operational reality, suggesting that transparency mandates may not capture the complexity of platform moderation.

Signal 7: Appeal Reversal Rates
YouTube's transparency report (December 2021) shows that 60% of takedown notices disputed by users in

the first half of 2021 were resolved in the user's favor [30]. This signal indicates high error rates in initial moderation decisions and suggests that procedural rights mechanisms can correct platform over-enforcement.

Signal 8: Regulatory Fragmentation Across Jurisdictions
The EU's comprehensive DSA contrasts sharply with U.S. regulatory stasis, where Section 230 debates produce political polarization but no federal reform [3]. This signal indicates divergent regulatory trajectories, with implications for platform compliance complexity and jurisdictional arbitrage.

Signal 9: Algorithmic Audit Professionalization
The DSA and UK Online Safety Act mandate independent algorithmic audits, creating an emerging "political economy of algorithmic auditing" dominated by traditional audit firms rather than technical specialists [29]. This signal suggests that regulatory mandates may be captured by existing professional structures rather than generating new forms of accountability.

Signal 10: Transparency Without Accountability
Multiple studies find that while the DSA mandates extensive transparency reporting, these mandates do not translate into concrete accountability mechanisms or enforcement actions [1], [14], [30]. This signal reveals a gap between information disclosure and regulatory effectiveness.

Signal 11: Platform-as-Utility Discourse Emergence
Scholarship increasingly frames social media platforms as public utilities requiring infrastructure-style regulation, emphasizing market structure and essential service characteristics [7]. This signal indicates a conceptual shift from content-focused regulation to structural governance.

Signal 12: Disinformation Regulation Limits
Studies assessing the DSA's impact on disinformation find that transparency mandates alone are insufficient to curb spread, as they do not address algorithmic amplification mechanisms or economic incentives [12], [13], [14]. This signal suggests limits to transparency-based regulatory approaches.

Signal 13: Procedural Rights Implementation Gaps
Despite DSA provisions for user rights, implementation reveals that platforms provide only partial procedural protections, lacking full administrative law standards for notice, explanation, and external review [11], [30]. This signal indicates that formal rights guarantees do not automatically translate into effective protections.

Signal 14: Systemic Risk Assessment Ambiguity
The DSA requires platforms to conduct systemic risk assessments, but the methodology, scope, and validation of these assessments remain contested, with platforms retaining significant discretion [12], [13], [21]. This signal reveals regulatory ambiguity in operationalizing abstract risk concepts.

Signal 15: Cross-Platform Moderation Variation
Analysis of DSA database records shows "substantial differences" in moderation actions across platforms, including variation in grounds for decision, types of restrictions, and automation use [2]. This signal indicates that platforms interpret and implement content policies heterogeneously, complicating efforts to establish consistent governance standards.

2.2 Counter-Signals (5)

Counter-Signal 1: Regulatory Compliance as Performance
Evidence suggests that platforms engage in "compliance theater," submitting data to the DSA database that satisfies formal requirements while obscuring actual moderation practices. The high inconsistency rates, particularly for X, indicate that transparency mandates may generate performative data rather than

genuine accountability [2], [5], [10]. This counter-signal challenges the assumption that mandated reporting produces reliable evidence.

Counter-Signal 2: Audit Capture by Traditional Firms
The professionalization of algorithmic auditing by traditional audit firms threatens to "erode important regulatory pillars" of the DSA, as these firms lack technical expertise and operate within "tight timelines" and "complex contractual arrangements" that dilute accountability [29]. This counter-signal suggests that regulatory mandates may be captured by incumbent professional structures, undermining their transformative potential.

Counter-Signal 3: Over-Blocking and Chilling Effects
The EU's Copyright Directive (CDSM) notice-and-takedown regime leads to "mass content removal due to platform risk-aversion, chilling free speech" [30]. Similarly, DSA compliance may incentivize over-moderation to avoid regulatory penalties, creating a counter-signal that transparency and accountability mandates can paradoxically reduce speech protections.

Counter-Signal 4: Transparency Overload Without Synthesis
The DSA Transparency Database generates massive data volumes (353 million records in 100 days), but this "information tsunami" exceeds the analytical capacity of regulators, researchers, and civil society to process meaningfully [8]. This counter-signal challenges the assumption that more transparency automatically improves governance, suggesting instead that data volume can obscure rather than illuminate.

Counter-Signal 5: Jurisdictional Arbitrage and Regulatory Evasion
Platforms can exploit jurisdictional differences by implementing minimal compliance in the EU while maintaining different practices elsewhere, or by restructuring operations to avoid VLOP designation [26]. This counter-signal indicates that territorial regulation of global platforms may be systematically evaded through corporate restructuring and strategic compliance.

2.3 Contested Signals (3)

Contested Signal 1: Automation as Efficiency vs. Rights Violation
TikTok's 92% automation rate in moderation is interpreted differently across regulatory grammars. Digital Constitutionalism views high automation as a procedural rights violation, denying users meaningful human review [30]. Algorithmic Public Health sees automation as necessary for scale and speed in harm reduction [2]. Platform Realism treats automation as an economic efficiency response to regulatory compliance costs [7]. The same empirical fact—92% automation—generates contradictory regulatory implications depending on the interpretive grammar applied.

Contested Signal 2: DSA Database Inconsistencies
The substantial data quality issues in the DSA Transparency Database are contested in their meaning. One interpretation holds that inconsistencies reveal platform resistance and bad-faith compliance, requiring stronger enforcement [2]. An alternative interpretation argues that inconsistencies reflect the genuine complexity of mapping diverse moderation practices onto a standardized reporting schema, indicating regulatory design flaws rather than platform malfeasance [5]. A third view suggests inconsistencies are inevitable in early implementation and will resolve over time through iterative refinement [23].

Contested Signal 3: Section 230 Reform Stalemate
The absence of U.S. federal Section 230 reform despite intense political debate is interpreted divergently. One view holds that stalemate reflects successful platform lobbying and regulatory capture [3]. Another interpretation argues that stalemate demonstrates appropriate caution about disrupting a legal framework that has enabled internet innovation and free expression [3]. A third perspective suggests that state-level experimentation is preferable to premature federal intervention [3]. The same empirical fact—no federal reform—supports contradictory narratives about regulatory wisdom.

Section 3: Grammar Identification

This analysis identifies three distinct regulatory grammars that organize the observation field differently, process signals through different interpretive frameworks, and generate different regulatory prescriptions:

Grammar 1: Digital Constitutionalism

Core Logic: Social media platforms exercise quasi-governmental power over digital public spheres and must therefore be constrained by constitutional principles—free expression, due process, procedural rights, and fundamental rights protections. Regulation should import administrative law principles into platform governance, ensuring that content moderation decisions are transparent, reasoned, appealable, and subject to external review.

Epistemic Foundation: Draws on constitutional law, administrative law, and human rights frameworks. Treats platforms as "private governors" whose power over speech requires legitimation through rights-based constraints. Emphasizes individual procedural protections over collective outcomes.

Key Proponents in Evidence Base: Carvalho [30], Geiger et al. [17], Jiang et al. [11], Lendvai et al. [3], Moustapha [21].

Regulatory Instruments: Transparency mandates, notice-and-explanation requirements, appeal mechanisms, external dispute resolution, algorithmic explainability, user rights frameworks.

Grammar 2: Algorithmic Public Health

Core Logic: Social media platforms function as vectors for societal harms—disinformation, hate speech, mental health impacts, radicalization—that spread through algorithmic amplification. Regulation should treat these harms as public health crises requiring preventive intervention, risk assessment, and harm reduction strategies. The focus is on systemic risks and collective safety rather than individual rights.

Epistemic Foundation: Draws on public health, risk regulation, and safety engineering frameworks. Treats harmful content as contagion and algorithmic amplification as the transmission mechanism. Emphasizes ex ante risk mitigation over ex post rights enforcement.

Key Proponents in Evidence Base: Monaci et al. [12], Nannini et al. [13], Quintas-Froufe et al. [6], Strowel et al. [14], Trujillo et al. [2].

Regulatory Instruments: Systemic risk assessments, content moderation mandates, algorithmic audits focused on amplification, transparency reports on harm prevalence, crisis response protocols.

Grammar 3: Platform Realism

Core Logic: Social media platforms are economic infrastructures characterized by network effects, market concentration, and structural power. Regulation should address market structure, competition dynamics, interoperability, and infrastructure governance rather than focusing narrowly on content. The problem is not what platforms moderate but their monopolistic control over digital communication infrastructure.

Epistemic Foundation: Draws on industrial organization economics, antitrust theory, and infrastructure studies. Treats platforms as essential facilities requiring structural regulation similar to utilities, telecommunications, or transportation networks. Emphasizes market structure over content governance.

Key Proponents in Evidence Base: Mueller-Bloch et al. [7], Ződi [26], Lodder et al. [8].

Regulatory Instruments: Interoperability mandates, data portability, structural separation, utility-style regulation, competition enforcement, infrastructure access requirements.

Section 4: Signal Processing

4.1 Grammar 1: Digital Constitutionalism

Processing Framework: Rights, Process, and Legitimacy

Digital Constitutionalism processes the observation field through a constitutional lens, treating social media regulation as fundamentally a question of legitimating private power over public discourse. This grammar begins with a foundational premise: platforms exercise quasi-governmental authority when they determine what speech is permissible in digital public spheres, and such authority requires constitutional constraints to be legitimate [17], [30].

Signal Integration: Procedural Rights as Regulatory Core

When Digital Constitutionalism encounters Signal 7—YouTube's 60% appeal reversal rate—it processes this as vindication of procedural rights mechanisms [30]. The high reversal rate demonstrates that initial moderation decisions are systematically erroneous, and that due process protections (notice, appeal, external review) can correct platform over-enforcement. This signal becomes evidence that procedural rights are not merely symbolic but functionally necessary to constrain platform power.

However, this grammar must simultaneously process Counter-Signal 3—evidence that procedural protections can incentivize over-blocking as platforms adopt risk-averse compliance strategies [30]. Digital Constitutionalism resolves this tension by distinguishing between *inadequate* procedural rights (which cause over-blocking) and *robust* procedural rights (which correct it). The solution is not less process but more: fuller explanations, faster appeals, genuinely independent external review, and meaningful remedies for wrongful takedowns.

Signal 13—procedural rights implementation gaps—is processed as a regulatory failure requiring stronger enforcement rather than a flaw in the constitutional approach itself [11], [30]. The DSA's procedural provisions are criticized not for being wrong-headed but for being insufficiently comprehensive. Carvalho argues that the DSA "failed to provide individual end users with procedural justice rights" equivalent to administrative law standards, and advocates importing full due process protections from public law into platform governance [30].

Transparency as Constitutional Accountability

Digital Constitutionalism processes transparency signals (1, 2, 6, 10) through a legitimacy framework. Transparency is valued not primarily for its informational content but for its constitutional function: making power visible and therefore accountable. When Signal 2 reveals that X's DSA database submissions are 99.8% focused on synthetic media—inconsistent with its transparency reports—Digital Constitutionalism interprets this as evidence of illegitimate power exercised in darkness [2].

The grammar processes Signal 10—transparency without accountability—as a problem of incomplete constitutionalization [1], [14]. Transparency mandates are necessary but insufficient; they must be coupled with enforcement mechanisms, sanctions for non-compliance, and institutional capacity for regulatory oversight. The solution is to strengthen the constitutional architecture: more detailed reporting requirements, independent auditors with enforcement power, and judicial review of platform decisions.

Counter-Signal 4—transparency overload—is processed as a technical implementation challenge rather than a conceptual flaw [8]. Digital Constitutionalism maintains that the problem is not too much transparency but inadequate institutional capacity to process it. The solution is to build regulatory infrastructure: specialized agencies, computational tools for analyzing transparency data, and standardized reporting formats that enable meaningful oversight.

Automation and the Right to Human Review

Signal 3—TikTok's 92% automation rate—is processed by Digital Constitutionalism as a fundamental rights violation [2]. Automated content moderation denies users the procedural right to human judgment, reducing speech governance to algorithmic black boxes that cannot provide reasoned explanations or respond to contextual nuance. This grammar treats automation as constitutionally suspect, requiring strict limitations and mandatory human review for consequential decisions.

This processing generates Contested Signal 1: whether automation is efficiency or rights violation. Digital Constitutionalism firmly sides with the rights violation interpretation, arguing that speed and scale cannot justify eliminating human judgment in speech governance [30]. The grammar processes automation as a form of "algorithmic due process denial" that must be constrained through regulatory mandates for human review, explainable AI, and contestability mechanisms.

However, this creates a tension with Signal 4—moderation delay patterns—which suggests that human review is resource-intensive and creates temporal lags [2]. Digital Constitutionalism resolves this by arguing that delays are acceptable costs of legitimate governance; speed cannot trump rights. The grammar rejects the premise that platforms must moderate at the scale and speed they currently do, suggesting instead that platforms should be required to design systems that enable human review, even if this means slower moderation or reduced content volumes.

Jurisdictional Divergence and Constitutional Pluralism

Signal 8—regulatory fragmentation between EU and U.S.—is processed by Digital Constitutionalism as reflecting different constitutional traditions [3]. The EU's comprehensive DSA embodies a European constitutional commitment to positive rights, state intervention, and social solidarity. The U.S. Section 230 framework reflects American constitutional commitments to negative liberty, minimal state interference, and market ordering.

This grammar does not necessarily view one approach as superior but recognizes them as different constitutional settlements. However, it processes Contested Signal 3—Section 230 reform stalemate—as problematic because it leaves platform power unconstrained by any constitutional framework [3]. The absence of regulation is not constitutional neutrality but rather a delegation of constitutional authority to private corporations without legitimating constraints.

Digital Constitutionalism processes Counter-Signal 5—jurisdictional arbitrage—as a challenge to constitutional sovereignty [26]. If platforms can evade EU constitutional constraints by restructuring operations or implementing minimal compliance, then constitutional rights become geographically contingent and practically unenforceable. The grammar's solution is to advocate for extraterritorial application of constitutional principles, international coordination, or structural regulations that prevent evasion.

Systemic Risk vs. Individual Rights

Signal 14—systemic risk assessment ambiguity—creates tension for Digital Constitutionalism [12], [13], [21]. The DSA's systemic risk framework shifts regulatory focus from individual content decisions to platform-level design and algorithmic amplification. This grammar is ambivalent about this shift: it welcomes

attention to structural platform power but worries that systemic risk discourse can justify restrictions on individual speech in the name of collective safety.

Digital Constitutionalism processes systemic risk provisions cautiously, insisting that any platform design changes mandated by risk assessments must respect individual speech rights. The grammar rejects utilitarian trade-offs where individual expression is sacrificed for aggregate harm reduction. This creates friction with Algorithmic Public Health grammar, which prioritizes collective safety over individual rights.

Cross-Platform Variation and Constitutional Consistency

Signal 15—substantial differences in moderation across platforms—is processed by Digital Constitutionalism as both inevitable and problematic [2]. Inevitable because platforms have different community standards, business models, and user bases; problematic because constitutional rights should not vary arbitrarily based on which platform a user chooses.

This grammar advocates for minimum constitutional standards that apply across all platforms—baseline procedural rights, transparency requirements, and due process protections—while allowing platforms to exceed these minimums. The goal is constitutional consistency without mandating identical content policies. However, this creates practical challenges: how to define minimum standards that are meaningful across diverse platform contexts without becoming either too vague or too prescriptive.

Limitations and Boundary Conditions

Digital Constitutionalism faces several limitations revealed by the signal processing:

First, it struggles with scale. Procedural rights mechanisms designed for individual cases (notice, explanation, appeal, review) become unwieldy when applied to billions of content moderation decisions annually. Signal 1—353 million moderation records in 100 days—suggests that meaningful human review of each decision is practically impossible [2]. The grammar's response—that platforms should moderate less or invest more in human review—may be economically or operationally infeasible.

Second, it has difficulty processing collective harms. Digital Constitutionalism's focus on individual rights makes it less equipped to address systemic issues like algorithmic amplification of disinformation, coordinated inauthentic behavior, or platform design features that harm mental health at population scale. Signal 12—disinformation regulation limits—suggests that individual rights frameworks may be insufficient for collective harm problems [12], [13], [14].

Third, it faces enforcement challenges. Counter-Signal 1—compliance as performance—reveals that platforms can satisfy formal procedural requirements while evading substantive accountability [2], [5], [10]. Constitutional rights are only as strong as their enforcement mechanisms, and the DSA's reliance on platform self-reporting and under-resourced regulators may be inadequate.

Closure Dynamics

Digital Constitutionalism achieves closure by treating procedural rights as non-negotiable foundations. When confronted with counter-signals or contested interpretations, this grammar returns to constitutional first principles: speech is a fundamental right, power requires legitimation, process is essential to legitimacy. This provides normative clarity but can make the grammar inflexible when confronting trade-offs between rights and other values (safety, privacy, competition).

The grammar's closure mechanism is to expand the constitutional framework rather than abandon it. When transparency proves insufficient, the solution is more robust transparency plus enforcement. When procedural rights are inadequately implemented, the solution is stronger procedural protections. When automation threatens due process, the solution is to mandate human review. This recursive expansion can

make Digital Constitutionalism increasingly demanding and potentially impractical, but it maintains internal coherence by refusing to compromise on constitutional fundamentals.

4.2 Grammar 2: Algorithmic Public Health

Processing Framework: Risk, Harm, and Systemic Intervention

Algorithmic Public Health processes the observation field through an epidemiological lens, treating social media platforms as vectors for societal harms that spread through algorithmic amplification. This grammar begins with a foundational premise: harmful content (disinformation, hate speech, violent extremism, mental health impacts) functions like contagion, and platforms' algorithmic recommendation systems are the transmission mechanism that enables exponential spread [2], [6], [12], [13], [14].

Signal Integration: Moderation Volume as Harm Prevalence

When Algorithmic Public Health encounters Signal 1—353 million moderation records in 100 days—it processes this as evidence of massive harm prevalence requiring systematic intervention [2]. The sheer volume of content requiring moderation demonstrates that harmful content is not a marginal problem but a structural feature of platform ecosystems. This signal justifies comprehensive regulatory intervention analogous to public health measures: surveillance (transparency reporting), diagnosis (risk assessment), and treatment (content moderation mandates).

Signal 15—cross-platform moderation variation—is processed as evidence of inconsistent harm reduction, analogous to varying public health standards across jurisdictions [2]. Algorithmic Public Health views this variation as problematic because harms (disinformation, hate speech) have consistent effects regardless of platform, yet platforms apply different standards. The grammar advocates for harmonized content policies based on evidence about harm, similar to how public health regulations standardize safety requirements.

Automation as Necessary Scalability

Algorithmic Public Health processes Signal 3—TikTok's 92% automation rate—entirely differently than Digital Constitutionalism [2]. This grammar views automation as necessary and appropriate for harm reduction at scale. Just as public health surveillance systems use automated monitoring (disease tracking, water quality sensors), content moderation must employ automation to detect and remove harmful content before it spreads virally.

This generates Contested Signal 1: automation as efficiency vs. rights violation. Algorithmic Public Health firmly sides with the efficiency interpretation, arguing that manual review is too slow to prevent harm propagation. The grammar processes automation not as a rights concern but as a technical requirement for effective intervention. However, it acknowledges that automation must be accurate—false positives and false negatives are problems of diagnostic precision, not fundamental objections to automated systems.

Signal 4—moderation delay patterns—is processed as a public health failure [2]. Pinterest's 7% of actions taking over 24 hours represents a dangerous lag during which harmful content can spread. Algorithmic Public Health prioritizes speed, viewing delays as analogous to slow outbreak response that allows disease to spread. The grammar advocates for faster automated detection and immediate intervention, accepting some over-moderation as preferable to under-moderation.

Transparency as Epidemiological Surveillance

Algorithmic Public Health processes transparency signals (1, 2, 6, 10) through a surveillance framework. Transparency is valued for its informational content—enabling regulators, researchers, and platforms themselves to track harm prevalence, identify emerging threats, and evaluate intervention effectiveness.

The DSA Transparency Database functions as an epidemiological surveillance system, making visible the "disease burden" of harmful content [2], [5], [15], [16], [23], [27].

When Signal 2 reveals platform reporting inconsistencies, Algorithmic Public Health processes this as a data quality problem that undermines surveillance effectiveness [2]. Inconsistent reporting is analogous to unreliable disease reporting that prevents accurate outbreak tracking. The grammar's solution is to standardize reporting protocols, validate data quality, and potentially impose penalties for inaccurate submissions—similar to public health reporting requirements.

Counter-Signal 4—transparency overload—is processed as a data management challenge requiring better analytical infrastructure [8]. Algorithmic Public Health does not view massive data volumes as problematic per se; epidemiological surveillance routinely handles large datasets. The solution is to develop computational tools, machine learning models, and visualization systems that can process transparency data to identify patterns, trends, and emerging risks.

Systemic Risk Assessment as Preventive Medicine

Signal 14—systemic risk assessment ambiguity—is central to Algorithmic Public Health's regulatory approach [12], [13], [21]. The DSA's requirement that platforms assess and mitigate systemic risks aligns perfectly with this grammar's preventive intervention logic. Systemic risk assessment is analogous to public health risk assessment: identifying populations at risk, transmission pathways, and intervention points before harms materialize.

However, the grammar must process the ambiguity and contestation surrounding risk assessment methodology. Algorithmic Public Health advocates for evidence-based risk assessment drawing on social science research about harm mechanisms: how disinformation spreads, how hate speech escalates to violence, how algorithmic amplification affects mental health. The grammar views platform discretion in risk assessment as problematic, preferring standardized, scientifically validated methodologies overseen by regulatory authorities.

Signal 12—disinformation regulation limits—is processed as evidence that transparency alone is insufficient for harm reduction [12], [13], [14]. Algorithmic Public Health interprets this signal as demonstrating that surveillance (transparency) must be coupled with intervention (content moderation, algorithmic modification). The grammar advocates for regulatory mandates that require platforms to modify recommendation algorithms to reduce harmful content amplification, analogous to requiring environmental modifications to reduce disease transmission.

Language Disparities as Health Inequity

Signal 5—language disparities in moderation workforce—is processed by Algorithmic Public Health as a health equity issue [25]. Minority language communities receiving less moderation capacity means they experience higher exposure to harmful content, creating disparate harm burdens analogous to health disparities in underserved populations. The grammar advocates for resource allocation requirements that ensure equitable harm reduction across linguistic and geographic communities.

This processing reveals a tension: equitable moderation requires massive investment in multilingual human moderators, but Signal 3 shows platforms rely heavily on automation [2]. Algorithmic Public Health resolves this by advocating for better multilingual AI systems and targeted human review for high-risk content in under-resourced languages. The grammar treats this as a technical challenge requiring investment rather than a fundamental limitation.

Jurisdictional Divergence as Regulatory Diffusion

Signal 8—EU-U.S. regulatory fragmentation—is processed by Algorithmic Public Health as analogous to varying public health regulations across jurisdictions [3]. The grammar views the EU's comprehensive approach as more effective harm reduction, similar to how some jurisdictions have stronger public health regulations. However, it recognizes that platform harms are global, requiring international coordination analogous to global health governance (WHO, international disease surveillance).

Contested Signal 3—Section 230 reform stalemate—is processed as a regulatory failure that leaves harms unaddressed [3]. Algorithmic Public Health views the U.S. approach as analogous to refusing to regulate a public health threat due to political gridlock. The grammar advocates for federal intervention to establish baseline harm reduction standards, viewing state-level fragmentation as inadequate for addressing platform-scale harms.

Counter-Signals and Iatrogenic Harms

Algorithmic Public Health must process Counter-Signal 3—over-blocking and chilling effects—which suggests that aggressive content moderation can cause iatrogenic harms (harms caused by the intervention itself) [30]. The grammar acknowledges this risk but processes it through a harm-balancing framework: some over-moderation is acceptable if it prevents greater harms from under-moderation. This is analogous to accepting side effects from medical interventions when the disease is more dangerous than the treatment.

However, this creates tension with Digital Constitutionalism, which views over-blocking as a fundamental rights violation rather than an acceptable trade-off. Algorithmic Public Health's utilitarian logic—maximizing aggregate welfare by minimizing total harm—conflicts with rights-based frameworks that prioritize individual protections over collective outcomes.

Counter-Signal 1—compliance as performance—is processed as a regulatory enforcement problem [2], [5], [10]. Algorithmic Public Health views performative compliance as analogous to fraudulent public health reporting, requiring stronger verification mechanisms and penalties. The grammar advocates for independent audits, random sampling, and cross-validation of platform-reported data to ensure accuracy.

Counter-Signal 2—audit capture by traditional firms—is particularly problematic for Algorithmic Public Health [29]. The grammar relies on algorithmic audits to verify that platforms are effectively reducing harms, but if audits are conducted by firms lacking technical expertise or operating under tight timelines, they cannot fulfill this function. Algorithmic Public Health advocates for specialized technical auditors with public health and computational expertise, potentially housed within regulatory agencies rather than private firms.

Contested Interpretations and Boundary Disputes

Contested Signal 2—DSA database inconsistencies—generates different interpretations within Algorithmic Public Health [2], [5], [23]. One interpretation views inconsistencies as evidence of platform resistance requiring stronger enforcement. Another views them as reflecting the genuine complexity of mapping diverse harms onto standardized categories, suggesting that reporting schemas need refinement based on epidemiological principles.

The grammar must also process the contested boundary between harmful and legitimate content. Unlike infectious disease (where the pathogen is clearly defined), content harms involve normative judgments about what constitutes disinformation, hate speech, or harmful speech. Algorithmic Public Health attempts to resolve this through evidence-based harm definitions: content is harmful if it demonstrably causes measurable negative outcomes (violence, mental health impacts, democratic dysfunction). However, this evidence-based approach faces challenges when harms are diffuse, long-term, or contested.

Limitations and Boundary Conditions

Algorithmic Public Health faces several limitations revealed by signal processing:

First, it struggles with normative pluralism. Public health frameworks assume consensus about what constitutes harm, but content harms are deeply contested across cultural, political, and ideological lines. What one community views as harmful disinformation, another views as legitimate political speech. The grammar's evidence-based approach cannot fully resolve these normative disputes.

Second, it risks paternalism. Public health interventions can be coercive, restricting individual autonomy for collective benefit. When applied to speech, this raises concerns about state or platform paternalism—deciding what information people should be exposed to "for their own good." Digital Constitutionalism views this as illegitimate; Algorithmic Public Health views it as necessary harm reduction.

Third, it faces measurement challenges. Unlike infectious disease (where cases can be counted), content harms are difficult to measure. How do you quantify the harm from a piece of disinformation or a hate speech post? Signal 12 suggests that even with extensive transparency data, assessing regulatory effectiveness in reducing harms remains difficult [12], [13], [14].

Closure Dynamics

Algorithmic Public Health achieves closure by treating harm reduction as the paramount regulatory goal. When confronted with counter-signals or contested interpretations, this grammar returns to consequentialist first principles: regulation should minimize aggregate harm, even if this requires restricting some speech, accepting some over-moderation, or prioritizing collective safety over individual rights.

The grammar's closure mechanism is to demand better evidence. When interventions prove ineffective (Signal 12), the solution is more rigorous research on harm mechanisms and intervention effectiveness [12], [13], [14]. When data quality is poor (Signal 2), the solution is better surveillance infrastructure [2]. When automation causes errors, the solution is more accurate AI systems. This evidence-based recursion maintains internal coherence but can make Algorithmic Public Health increasingly technocratic, relying on expert judgment that may not reflect democratic values or community preferences.

4.3 Grammar 3: Platform Realism

Processing Framework: Structure, Power, and Infrastructure

Platform Realism processes the observation field through a political economy lens, treating social media regulation as fundamentally a question of market structure and infrastructural power. This grammar begins with a foundational premise: the problem is not what platforms moderate or how they moderate, but that a small number of corporations exercise monopolistic control over essential digital communication infrastructure [7], [26].

Signal Integration: Moderation Volume as Market Power Indicator

When Platform Realism encounters Signal 1—353 million moderation records in 100 days—it processes this as evidence of concentrated infrastructural power [2]. The fact that eight platforms collectively make hundreds of millions of content governance decisions demonstrates their role as essential infrastructure for digital communication. This signal justifies structural regulation analogous to utility regulation: treating platforms as common carriers or essential facilities subject to non-discrimination requirements, interoperability mandates, and structural oversight.

Signal 15—cross-platform moderation variation—is processed entirely differently by Platform Realism than by other grammars [2]. Rather than viewing variation as inconsistent harm reduction (Algorithmic Public Health) or arbitrary rights application (Digital Constitutionalism), Platform Realism views it as evidence of market power. Each platform can impose its own content rules because users lack meaningful alternatives;

switching costs, network effects, and data lock-in prevent competitive discipline. The grammar's solution is not to harmonize content policies but to reduce market concentration through structural interventions.

Automation as Cost Externalization

Platform Realism processes Signal 3—TikTok's 92% automation rate—as an economic efficiency strategy that externalizes costs [2]. Platforms automate moderation not primarily for speed or scale but to minimize labor costs. This grammar views automation as a business decision driven by profit maximization rather than a technical necessity or rights concern. The high automation rate reflects platforms' market power: they can impose algorithmic governance on users because users lack alternatives.

This generates Contested Signal 1 from a third angle. Platform Realism views automation neither as efficiency (Algorithmic Public Health) nor rights violation (Digital Constitutionalism) but as a symptom of market failure. In a competitive market, platforms would compete on moderation quality, investing in human review to attract users. The fact that they don't suggests market concentration allows them to minimize costs without losing users. The grammar's solution is structural: increase competition so platforms must compete on governance quality.

Signal 4—moderation delay patterns—is processed as evidence of under-investment in governance infrastructure [2]. Pinterest's delays reflect a business decision to allocate resources to growth and engagement rather than moderation. Platform Realism views this as rational profit-maximizing behavior in a concentrated market where platforms face limited competitive pressure to improve governance. The grammar advocates for utility-style regulation that mandates minimum service quality standards, including moderation timeliness.

Transparency as Market Information

Platform Realism processes transparency signals (1, 2, 6, 10) through a market information framework. Transparency is valued for enabling users, advertisers, and regulators to assess platform governance quality and make informed decisions. The DSA Transparency Database functions as a market information mechanism, making visible platform behavior that was previously opaque [2], [5], [15], [16], [23], [27].

However, Signal 10—transparency without accountability—is processed by Platform Realism as evidence that information disclosure alone cannot discipline market power [1], [14]. In competitive markets, transparency enables users to switch to better-governed platforms. But network effects and switching costs mean transparency doesn't generate competitive pressure. The grammar's solution is structural: mandating interoperability and data portability so users can actually switch platforms based on governance preferences.

Counter-Signal 4—transparency overload—is processed as a design flaw in transparency mandates [8]. Platform Realism views the DSA's approach as generating unusable data volumes because it focuses on individual content decisions rather than structural platform characteristics. The grammar advocates for transparency focused on market structure: platform ownership, revenue sources, algorithmic ranking principles, data practices, and interoperability capabilities. This structural transparency would be more useful for assessing market power than granular moderation data.

Jurisdictional Divergence as Regulatory Competition

Signal 8—EU-U.S. regulatory fragmentation—is processed by Platform Realism as regulatory competition that platforms can exploit [3]. The grammar views jurisdictional differences not as reflecting different constitutional traditions but as creating arbitrage opportunities. Platforms can threaten to relocate operations, restructure corporate entities, or reduce services in jurisdictions with stricter regulation. This dynamic gives platforms structural power over regulators.

Counter-Signal 5—jurisdictional arbitrage and regulatory evasion—is central to Platform Realism's analysis [26]. The grammar views territorial regulation of global platforms as fundamentally limited because platforms can restructure to evade jurisdiction. The solution is not stronger territorial enforcement but structural regulation that cannot be evaded: mandating interoperability (which benefits users regardless of platform location), requiring data portability (which reduces lock-in), or imposing structural separation (which limits platform power directly).

Contested Signal 3—Section 230 reform stalemate—is processed by Platform Realism as reflecting platform lobbying power rather than principled disagreement [3]. The grammar views Section 230 as a subsidy to platforms that enables their business models by exempting them from liability. The stalemate reflects platforms' political power to block reform, demonstrating how market concentration translates into political influence. Platform Realism advocates for antitrust enforcement and structural remedies rather than content regulation.

Systemic Risk as Market Failure

Signal 14—systemic risk assessment ambiguity—is processed by Platform Realism as misdiagnosing the problem [12], [13], [21]. The grammar views "systemic risks" not as content-related harms but as structural features of concentrated platform markets: algorithmic manipulation, data exploitation, anti-competitive practices, and infrastructure fragility. The DSA's focus on content-related systemic risks (disinformation, hate speech) distracts from the fundamental problem of market structure.

Platform Realism processes Signal 12—disinformation regulation limits—as evidence that content-focused regulation cannot address structural problems [12], [13], [14]. Disinformation spreads not because platforms fail to moderate it but because their business models incentivize engagement-maximizing algorithms that amplify sensational content. The grammar's solution is not better content moderation but structural intervention: prohibiting engagement-based ranking, mandating chronological feeds, or requiring algorithmic transparency that enables users to choose their own ranking criteria.

Language Disparities as Infrastructure Inequality

Signal 5—language disparities in moderation workforce—is processed by Platform Realism as evidence of infrastructure inequality [25]. Platforms invest in moderation capacity for profitable markets (English, major European languages) while under-serving less profitable linguistic communities. This reflects rational business decisions in concentrated markets where platforms don't face competitive pressure to serve all communities equally.

The grammar's solution is utility-style regulation mandating universal service obligations. Just as telecommunications regulation requires carriers to serve rural and unprofitable areas, platform regulation should require equitable governance infrastructure across linguistic and geographic communities. This is not a content moderation mandate but an infrastructure investment requirement.

Platform-as-Utility Discourse

Signal 11—platform-as-utility discourse emergence—is central to Platform Realism's regulatory vision [7]. The grammar views social media platforms as essential infrastructure analogous to electricity, telecommunications, or transportation networks. This framing justifies comprehensive structural regulation: rate regulation (limiting platform fees), common carriage (non-discrimination in service provision), interoperability (enabling competition), and public utility oversight.

Mueller-Bloch et al. [7] articulate this grammar explicitly, arguing that platforms should be governed as public utilities. This processing reframes all other signals: moderation volume becomes a question of infrastructure capacity, automation becomes a service delivery mechanism, transparency becomes utility reporting, and jurisdictional issues become questions of infrastructure governance. The grammar shifts

focus from content to structure, from moderation to market power, from individual rights to collective infrastructure.

Counter-Signals and Regulatory Capture

Platform Realism must process Counter-Signal 2—audit capture by traditional firms—as evidence of regulatory capture more broadly [29]. The grammar views the professionalization of algorithmic auditing by traditional audit firms as reflecting platforms' ability to shape regulatory implementation. Just as regulated utilities often capture their regulators, platforms are capturing the audit ecosystem, ensuring that audits are conducted by firms with limited technical expertise and strong commercial incentives to maintain client relationships.

The grammar's solution is structural: public auditing capacity housed within regulatory agencies, mandatory disclosure of audit methodologies and findings, and prohibition of auditors providing other services to audited platforms (to prevent conflicts of interest). Platform Realism views independent technical capacity as essential for effective structural regulation.

Counter-Signal 1—compliance as performance—is processed as expected behavior in concentrated markets [2], [5], [10]. Platform Realism views performative compliance as rational: platforms minimize compliance costs while maintaining market position. The grammar does not view this as a moral failure but as predictable behavior given market structure. The solution is not stronger enforcement of existing mandates but structural interventions that change platform incentives: competition that rewards genuine governance quality, interoperability that enables users to switch, or utility regulation that mandates service standards.

Contested Interpretations and Structural Diagnosis

Contested Signal 2—DSA database inconsistencies—is processed by Platform Realism as evidence that content-focused regulation is misguided [2], [5], [23]. The grammar views data quality issues not as implementation problems but as symptoms of trying to regulate platform behavior through transparency mandates rather than structural interventions. Platforms will always find ways to comply minimally with reporting requirements while maintaining their core business models.

Platform Realism advocates for shifting regulatory focus from content moderation transparency to structural transparency: ownership structures, revenue sources, algorithmic ranking principles, data collection practices, and interoperability capabilities. This structural information is more relevant for assessing market power and designing effective interventions.

Limitations and Boundary Conditions

Platform Realism faces several limitations revealed by signal processing:

First, it struggles with content-specific harms. While the grammar effectively diagnoses market structure problems, it has less to say about immediate content harms (terrorist content, child sexual abuse material, targeted harassment). Structural interventions like interoperability or competition take years to implement, while content harms require immediate response. The grammar risks appearing indifferent to urgent safety concerns.

Second, it faces political feasibility challenges. Structural interventions like breaking up platforms, mandating interoperability, or imposing utility regulation face intense political opposition and legal challenges. The grammar's solutions may be theoretically sound but practically difficult to implement, especially in the U.S. where antitrust enforcement has been weak for decades.

Third, it must confront the possibility that competition might not improve governance. If platforms compete primarily on engagement rather than governance quality, increased competition could lead to a "race to the

bottom" where platforms reduce moderation to maximize user engagement. Platform Realism must explain why competition would generate better governance rather than worse.

Closure Dynamics

Platform Realism achieves closure by treating market structure as the fundamental determinant of platform behavior. When confronted with counter-signals or contested interpretations, this grammar returns to structural first principles: concentrated markets generate predictable pathologies (under-investment in governance, user exploitation, regulatory capture), and only structural interventions can address these pathologies.

The grammar's closure mechanism is to reframe content-focused problems as structural problems. When content moderation is inadequate, the problem is market concentration allowing platforms to under-invest. When transparency is performative, the problem is lack of competitive pressure. When automation causes errors, the problem is cost minimization in concentrated markets. This structural recursion maintains internal coherence but can make Platform Realism appear to have a single solution (structural intervention) for all problems, potentially oversimplifying complex governance challenges.

Section 5: Closure Comparison

The three regulatory grammars achieve closure—stable interpretive frameworks that process signals into coherent regulatory narratives—through fundamentally different mechanisms. Comparing these closure dynamics reveals how each grammar maintains internal coherence while generating incompatible regulatory prescriptions.

5.1 Closure Mechanisms

Digital Constitutionalism: Normative Anchoring

Digital Constitutionalism achieves closure by anchoring interpretation in non-negotiable constitutional principles: free expression, due process, procedural rights, and fundamental rights protections [17], [30]. When confronted with ambiguous signals or counter-evidence, this grammar returns to these normative foundations. The 60% appeal reversal rate (Signal 7) is processed as vindicating procedural rights; over-blocking (Counter-Signal 3) is processed as evidence of inadequate procedural protections; automation (Signal 3) is processed as rights violation [2], [30].

This normative anchoring provides stability: regardless of empirical complexity, Digital Constitutionalism maintains that certain principles are inviolable. However, this creates rigidity. The grammar struggles to process trade-offs between rights and other values (safety, efficiency, collective welfare). When Algorithmic Public Health argues that some over-moderation is acceptable to prevent greater harms, Digital Constitutionalism cannot accept this utilitarian logic without abandoning its constitutional foundations.

The closure mechanism is recursive expansion: when existing procedural protections prove inadequate, the solution is stronger procedural protections. When transparency doesn't generate accountability, the solution is more robust transparency plus enforcement. This recursion maintains coherence but generates increasingly demanding regulatory requirements that may be practically infeasible.

Algorithmic Public Health: Evidence-Based Optimization

Algorithmic Public Health achieves closure through evidence-based optimization: regulation should minimize aggregate harm based on empirical evidence about harm mechanisms and intervention effectiveness [2], [6], [12], [13], [14]. When confronted with ambiguous signals, this grammar demands

better evidence. The 353 million moderation records (Signal 1) are processed as surveillance data enabling harm tracking; inconsistencies (Signal 2) are processed as data quality problems requiring better measurement; disinformation regulation limits (Signal 12) are processed as evidence that interventions need refinement [2], [12], [13], [14].

This evidence-based anchoring provides adaptability: as new evidence emerges about harm mechanisms, regulatory approaches can be updated. However, this creates instability. The grammar's prescriptions depend on contested empirical claims about what constitutes harm, how harms spread, and what interventions are effective. When evidence is ambiguous or contested, the grammar lacks clear guidance.

The closure mechanism is technocratic recursion: when interventions prove ineffective, the solution is better research, more sophisticated measurement, and refined interventions. When automation causes errors, the solution is more accurate AI. When transparency data is overwhelming, the solution is better analytical tools. This recursion maintains coherence but generates increasingly technocratic governance that may not reflect democratic values or community preferences.

Platform Realism: Structural Determinism

Platform Realism achieves closure through structural determinism: platform behavior is determined by market structure, and only structural interventions can change behavior [7], [26]. When confronted with ambiguous signals, this grammar reframes them as symptoms of market concentration. Inadequate moderation reflects under-investment in concentrated markets; performative compliance reflects lack of competitive pressure; automation reflects cost minimization without competitive discipline [2], [7].

This structural anchoring provides parsimony: a single explanatory framework (market structure) accounts for diverse phenomena. However, this creates reductionism. The grammar risks treating all governance problems as market structure problems, potentially overlooking content-specific issues, cultural factors, or institutional dynamics that cannot be reduced to market concentration.

The closure mechanism is structural recursion: when content regulation proves ineffective, the solution is structural intervention. When transparency doesn't generate accountability, the solution is interoperability enabling competitive discipline. When platforms capture auditors, the solution is public audit capacity. This recursion maintains coherence but generates a single-solution framework that may oversimplify complex governance challenges.

5.2 Incompatible Prescriptions

The three grammars process the same signals into incompatible regulatory prescriptions:

Automation (Signal 3, Contested Signal 1)

- Digital Constitutionalism: Mandate human review for consequential decisions; limit automation to preserve procedural rights; require explainable AI and contestability mechanisms [30].
- Algorithmic Public Health: Embrace automation as necessary for harm reduction at scale; invest in more accurate AI systems; accept some errors as inevitable in preventive intervention [2].
- Platform Realism: View automation as cost minimization in concentrated markets; increase competition so platforms must compete on governance quality; mandate service standards including moderation timeliness [7].

These prescriptions are mutually incompatible. Digital Constitutionalism's human review mandates conflict with Algorithmic Public Health's embrace of automation. Platform Realism's structural interventions (competition, interoperability) operate on different timescales and mechanisms than either content-focused approach.

Transparency (Signals 1, 2, 6, 10, Counter-Signal 4)

- Digital Constitutionalism: Strengthen transparency mandates; couple with enforcement mechanisms; build regulatory capacity to process transparency data; ensure transparency serves accountability [1], [14], [30].
- Algorithmic Public Health: Standardize transparency reporting for epidemiological surveillance; validate data quality; develop computational tools to process large datasets; focus transparency on harm prevalence and intervention effectiveness [2], [12], [13], [14].
- Platform Realism: Shift transparency focus from content moderation to market structure; mandate disclosure of ownership, revenue sources, algorithmic principles, and interoperability capabilities; view content moderation transparency as generating unusable data volumes [7], [8].

These prescriptions reflect different theories of what transparency is for: constitutional accountability (Digital Constitutionalism), epidemiological surveillance (Algorithmic Public Health), or market information (Platform Realism). Each grammar views the others' transparency priorities as misguided.

Jurisdictional Fragmentation (Signal 8, Contested Signal 3, Counter-Signal 5)

- Digital Constitutionalism: Recognize jurisdictional differences as reflecting different constitutional traditions; advocate for minimum constitutional standards with room for variation; address arbitrage through extraterritorial application or international coordination [3].
- Algorithmic Public Health: View fragmentation as undermining global harm reduction; advocate for international coordination analogous to global health governance; establish evidence-based harm standards that transcend jurisdictions [3], [12], [13].
- Platform Realism: View fragmentation as creating arbitrage opportunities that platforms exploit; advocate for structural interventions (interoperability, data portability) that cannot be evaded through jurisdictional restructuring; focus on market structure rather than territorial regulation [3], [26].

These prescriptions reflect different theories of regulatory authority: constitutional sovereignty (Digital Constitutionalism), global harm governance (Algorithmic Public Health), or structural intervention (Platform Realism).

5.3 Incommensurable Evidence Standards

The three grammars employ incommensurable evidence standards, making it impossible to adjudicate between them empirically:

Digital Constitutionalism evaluates regulation based on procedural adequacy: Are users provided notice, explanation, and appeal? Is there meaningful human review? Are fundamental rights protected? The 60% appeal reversal rate (Signal 7) is processed as evidence of success because procedural mechanisms corrected errors [30]. Evidence about aggregate harm reduction is less relevant than evidence about individual rights protection.

Algorithmic Public Health evaluates regulation based on harm reduction effectiveness: Does regulation reduce disinformation spread, hate speech prevalence, or mental health impacts? The grammar demands quantitative evidence about harm mechanisms and intervention effectiveness [12], [13], [14]. Evidence about procedural rights is less relevant than evidence about population-level outcomes.

Platform Realism evaluates regulation based on structural change: Does regulation reduce market concentration, enable competition, or limit platform power? The grammar demands evidence about market structure, switching costs, and competitive dynamics [7], [26]. Evidence about content moderation or individual rights is less relevant than evidence about infrastructural power.

These evidence standards are incommensurable: success by one grammar's standards may be failure by another's. A regulation that protects procedural rights (Digital Constitutionalism success) but doesn't reduce harms (Algorithmic Public Health failure) and doesn't change market structure (Platform Realism failure) will be evaluated entirely differently depending on which grammar is applied.

5.4 Temporal Horizons and Intervention Logics

The three grammars operate on different temporal horizons:

Digital Constitutionalism focuses on immediate procedural protections. When a user's content is removed, they should receive immediate notice, explanation, and appeal rights. The temporal horizon is the individual moderation decision. This creates urgency: rights violations demand immediate remedy [30].

Algorithmic Public Health focuses on medium-term harm reduction. Interventions (content moderation, algorithmic modification) should reduce harm prevalence over weeks or months. The temporal horizon is the epidemic curve. This creates patience for interventions to take effect but urgency to prevent harm spread [2], [12], [13], [14].

Platform Realism focuses on long-term structural change. Interventions (interoperability mandates, competition enforcement, structural separation) may take years to implement and generate effects. The temporal horizon is market transformation. This creates patience for structural change but frustration with immediate content harms [7], [26].

These temporal horizons generate different intervention logics. Digital Constitutionalism demands immediate procedural protections; Algorithmic Public Health demands rapid harm reduction; Platform Realism demands patient structural transformation. A regulatory approach that satisfies one temporal logic may be inadequate by another's standards.

5.5 Boundary Conditions and Failure Modes

Each grammar has characteristic failure modes revealed by counter-signals:

Digital Constitutionalism fails when procedural rights become impractical at scale (Signal 1: 353 million decisions), when rights protections incentivize over-blocking (Counter-Signal 3), or when platforms engage in compliance theater (Counter-Signal 1) [2], [30]. The grammar's normative anchoring provides clarity but can generate infeasible requirements.

Algorithmic Public Health fails when harms are normatively contested rather than empirically measurable (Contested Signal 2), when interventions cause iatrogenic harms (Counter-Signal 3), or when evidence is ambiguous (Signal 12) [12], [13], [14], [30]. The grammar's evidence-based anchoring provides adaptability but can become technocratic or paternalistic.

Platform Realism fails when structural interventions are politically infeasible (Contested Signal 3), when competition doesn't improve governance (potential race to bottom), or when immediate content harms require rapid response (terrorist content, CSAM) [3], [7]. The grammar's structural anchoring provides parsimony but can appear indifferent to urgent safety concerns.

5.6 Synthesis Impossibility

The comparison reveals that synthesis across grammars is impossible without abandoning the core logic of at least one grammar. Attempts to combine them generate contradictions:

- A regulation that mandates human review (Digital Constitutionalism) conflicts with embracing automation for harm reduction (Algorithmic Public Health).

- A regulation that focuses on content moderation (Digital Constitutionalism, Algorithmic Public Health) conflicts with viewing content regulation as misguided distraction from market structure (Platform Realism).
- A regulation that prioritizes individual rights (Digital Constitutionalism) conflicts with utilitarian harm reduction that accepts rights trade-offs (Algorithmic Public Health).

The grammars are not complementary perspectives that can be integrated but competing frameworks that organize reality differently. Regulatory policy must choose which grammar to privilege, or attempt pragmatic compromises that satisfy none fully. The DSA itself reflects an unstable compromise: constitutional rights provisions (Digital Constitutionalism), systemic risk assessment (Algorithmic Public Health), and some structural elements (gatekeeper provisions), without fully committing to any single grammar's logic.

Section 6: Counter-Signals & Stress Test

This section subjects each regulatory grammar to systematic stress testing using the five counter-signals identified in Section 2.2, examining how each grammar processes evidence that contradicts or undermines its core assumptions.

6.1 Counter-Signal 1: Regulatory Compliance as Performance

Empirical Content: Platforms engage in "compliance theater," submitting data to the DSA Transparency Database that satisfies formal requirements while obscuring actual moderation practices. X's 99.8% focus on synthetic media is inconsistent with its transparency reports, suggesting strategic reporting rather than genuine disclosure. High inconsistency rates across platforms indicate that transparency mandates may generate performative data rather than reliable evidence [2], [5], [10].

Stress Test: Digital Constitutionalism

This counter-signal directly challenges Digital Constitutionalism's assumption that transparency mandates generate accountability. If platforms can satisfy formal procedural requirements while evading substantive accountability, then procedural rights become empty formalism. The grammar must confront the possibility that platforms are sophisticated institutional actors capable of "gaming" procedural requirements.

Digital Constitutionalism's response is to distinguish between *inadequate* procedural requirements (which enable gaming) and *robust* procedural requirements (which prevent it). The solution is more detailed mandates, stronger verification, and meaningful sanctions for non-compliance. However, this response generates a regulatory arms race: as requirements become more detailed, platforms develop more sophisticated compliance strategies. The grammar must explain why this arms race will eventually favor regulators rather than platforms.

The counter-signal reveals a deeper tension: procedural rights frameworks assume good-faith institutional actors who will comply with the spirit of requirements. When actors are strategic and adversarial, procedural protections may be insufficient. Digital Constitutionalism must either abandon its assumption of good faith or develop enforcement mechanisms that can detect and punish bad-faith compliance—potentially requiring intrusive regulatory oversight that conflicts with the grammar's emphasis on limiting state power.

Stress Test: Algorithmic Public Health

This counter-signal challenges Algorithmic Public Health's reliance on platform-reported data for epidemiological surveillance. If transparency data is performative rather than accurate, then harm

prevalence estimates, intervention effectiveness assessments, and risk evaluations are all compromised. The grammar's evidence-based approach requires reliable data, but Counter-Signal 1 suggests that mandated reporting may not generate reliability.

Algorithmic Public Health's response is to treat data quality as a technical problem requiring validation mechanisms: independent audits, random sampling, cross-validation against external data sources, and penalties for inaccurate reporting. The grammar advocates for building regulatory capacity to verify platform submissions, analogous to how public health agencies validate disease reporting.

However, this response requires substantial regulatory resources and technical expertise that may not exist. Counter-Signal 2 (audit capture) suggests that independent verification may be compromised. The grammar must confront the possibility that platforms' informational advantages are structural: they control the data infrastructure, determine what is measured, and can always know more about their systems than external auditors. This asymmetry may be irreducible, undermining the grammar's evidence-based foundations.

Stress Test: Platform Realism

This counter-signal is least problematic for Platform Realism, which expects performative compliance as rational behavior in concentrated markets. Platforms minimize compliance costs while maintaining market position—this is predictable given market structure. The grammar views compliance theater not as a moral failure but as evidence that content-focused regulation is misguided.

Platform Realism's response is to advocate for structural interventions that change platform incentives rather than mandating better reporting. If platforms face genuine competition, they must compete on governance quality; if users can easily switch platforms via interoperability, performative compliance becomes costly. The grammar views Counter-Signal 1 as vindicating its structural diagnosis.

However, this response faces a temporal problem: structural interventions take years to implement, while performative compliance undermines current regulation immediately. The grammar must explain what should be done in the interim, or accept that content-focused regulation will remain ineffective until market structure changes. This creates political vulnerability: if Platform Realism cannot address immediate governance failures, it may lose policy influence to grammars that promise faster solutions.

6.2 Counter-Signal 2: Audit Capture by Traditional Firms

Empirical Content: The professionalization of algorithmic auditing by traditional audit firms threatens to "erode important regulatory pillars" of the DSA. These firms lack technical expertise in algorithmic systems and operate within "tight timelines" and "complex contractual arrangements" that dilute accountability. Ambitious research ideas for algorithmic auditing may be "crashed by the standardising grip of traditional auditors" [29].

Stress Test: Digital Constitutionalism

This counter-signal challenges Digital Constitutionalism's assumption that independent audits can verify platform compliance with procedural rights requirements. If auditors lack technical expertise to assess algorithmic decision-making, they cannot determine whether platforms provide meaningful explanations, whether automated systems are biased, or whether appeal mechanisms are effective.

Digital Constitutionalism's response is to advocate for specialized auditors with technical expertise, potentially housed within regulatory agencies rather than private firms. The grammar emphasizes that auditor independence requires not just organizational separation but also technical capacity and freedom from commercial pressures. However, this response requires building public sector technical capacity that

currently doesn't exist, and faces political opposition from those who view private sector auditing as more efficient.

The counter-signal reveals a deeper tension: constitutional accountability requires external verification, but effective verification requires technical expertise that is concentrated in the private sector (often in the platforms themselves or firms with commercial relationships to platforms). Digital Constitutionalism must either accept compromised audits or advocate for massive public investment in technical regulatory capacity—a politically difficult position.

Stress Test: Algorithmic Public Health

This counter-signal is particularly damaging for Algorithmic Public Health, which relies on algorithmic audits to verify that platforms are effectively reducing harms. If audits are conducted by firms lacking technical expertise or operating under commercial pressures, they cannot assess whether recommendation algorithms amplify harmful content, whether automated moderation is accurate, or whether risk assessments are valid.

Algorithmic Public Health's response is to demand specialized technical auditors with public health and computational expertise. The grammar advocates for auditing methodologies that test algorithmic systems empirically—running experiments, analyzing recommendation patterns, measuring harm prevalence—rather than relying on document review or compliance checklists. However, this requires auditors with rare interdisciplinary expertise (computer science, statistics, social science) and access to platform systems that platforms may resist providing.

The counter-signal forces Algorithmic Public Health to confront a fundamental challenge: effective harm reduction requires understanding complex socio-technical systems (algorithms, user behavior, content ecosystems), but this understanding may be impossible for external auditors to achieve given platforms' informational advantages and auditors' resource constraints. The grammar must either accept limited audit effectiveness or advocate for regulatory powers that give auditors deep access to platform systems—potentially raising privacy and trade secret concerns.

Stress Test: Platform Realism

This counter-signal strongly supports Platform Realism's diagnosis that content-focused regulation will be captured by incumbent interests. The grammar views audit capture as predictable: platforms shape the audit ecosystem to ensure that audits are conducted by firms with limited technical capacity and strong incentives to maintain client relationships. This is analogous to how regulated utilities often capture their regulators.

Platform Realism's response is to argue that audit capture demonstrates the futility of content-focused regulation. If platforms can capture the audit process, they can evade accountability regardless of how detailed transparency mandates or procedural requirements become. The grammar advocates for structural interventions that don't depend on auditing: interoperability (which users can verify directly), data portability (which users can test), or structural separation (which is objectively verifiable).

However, this response may overstate the case. Even structural interventions require verification and enforcement, which face similar capture risks. Platform Realism must explain why structural regulation is less vulnerable to capture than content regulation, or accept that all regulation of powerful actors faces capture risks that cannot be eliminated through regulatory design alone.

6.3 Counter-Signal 3: Over-Blocking and Chilling Effects

Empirical Content: The EU's Copyright Directive notice-and-takedown regime leads to "mass content removal due to platform risk-aversion, chilling free speech." DSA compliance may incentivize

over-moderation to avoid regulatory penalties. AI-driven moderation lacks safeguards, creating potential for false positives and insufficient external review [30].

Stress Test: Digital Constitutionalism

This counter-signal creates a paradox for Digital Constitutionalism: procedural rights protections designed to constrain platform power may incentivize platforms to over-enforce, thereby restricting speech more than they would without regulation. The grammar must confront the possibility that its own prescriptions generate unintended consequences that undermine its constitutional goals.

Digital Constitutionalism's response is to distinguish between *inadequate* procedural protections (which cause over-blocking) and *robust* procedural protections (which prevent it). The grammar argues that over-blocking occurs when platforms face liability for under-enforcement but lack strong procedural safeguards for users. The solution is to balance enforcement incentives with robust appeal mechanisms, meaningful remedies for wrongful takedowns, and sanctions for over-enforcement.

However, this response may be theoretically sound but practically difficult. Platforms face asymmetric risks: under-enforcement can generate regulatory penalties, public criticism, and advertiser boycotts, while over-enforcement generates only individual user complaints that are costly to process. Even with robust procedural protections, platforms may rationally choose over-enforcement. Digital Constitutionalism must either accept some over-blocking as inevitable or advocate for regulatory mechanisms that penalize over-enforcement as severely as under-enforcement—which may be difficult to implement.

Stress Test: Algorithmic Public Health

This counter-signal challenges Algorithmic Public Health's utilitarian logic by revealing iatrogenic harms: interventions designed to reduce harm (content moderation) can cause different harms (over-blocking, chilling effects). The grammar must confront trade-offs between different types of harm rather than assuming that more intervention always reduces aggregate harm.

Algorithmic Public Health's response is to acknowledge trade-offs and advocate for optimizing the balance: some over-moderation is acceptable if it prevents greater harms from under-moderation. The grammar treats this as analogous to medical interventions that have side effects but are justified when the disease is more dangerous than the treatment. However, this utilitarian logic conflicts with Digital Constitutionalism's rights-based framework, which views over-blocking as a fundamental rights violation rather than an acceptable trade-off.

The counter-signal forces Algorithmic Public Health to specify how much over-blocking is acceptable and who decides. If platforms over-moderate to minimize their regulatory risk, they are making utilitarian calculations that prioritize their interests over aggregate welfare. The grammar must either accept platform discretion in balancing harms or advocate for regulatory specification of acceptable error rates—which requires quantifying the relative harms of over- vs. under-moderation, a normatively contested exercise.

Stress Test: Platform Realism

This counter-signal supports Platform Realism's argument that content-focused regulation generates perverse incentives. Platforms over-moderate because they face regulatory pressure to remove harmful content but lack competitive pressure to preserve legitimate speech. In concentrated markets, users cannot switch to less restrictive platforms, so platforms face no market discipline for over-enforcement.

Platform Realism's response is to advocate for structural interventions that create competitive pressure for balanced moderation. If users can easily switch platforms via interoperability, platforms must compete on governance quality, balancing safety and free expression to attract users. The grammar views over-blocking as a symptom of market failure rather than a regulatory design flaw.

However, this response faces an empirical challenge: would competition actually generate better moderation balance, or would platforms compete on engagement maximization regardless of governance quality? Platform Realism must provide evidence that competition improves governance, not just assume it. Counter-Signal 3 suggests that regulatory pressure (not market structure) drives over-blocking, which complicates the grammar's structural diagnosis.

6.4 Counter-Signal 4: Transparency Overload Without Synthesis

Empirical Content: The DSA Transparency Database generates massive data volumes (353 million records in 100 days), creating an "information tsunami" that exceeds the analytical capacity of regulators, researchers, and civil society to process meaningfully. Data volume can obscure rather than illuminate [8].

Stress Test: Digital Constitutionalism

This counter-signal challenges Digital Constitutionalism's assumption that transparency generates accountability. If transparency data is too voluminous to process, it cannot enable meaningful oversight. The grammar must confront the possibility that mandating more information does not automatically improve accountability and may actually reduce it by overwhelming oversight capacity.

Digital Constitutionalism's response is to treat transparency overload as a technical implementation challenge requiring better tools: computational analysis, visualization systems, standardized reporting formats, and regulatory capacity building. The grammar maintains that the problem is not too much transparency but inadequate infrastructure to process it. However, this response requires substantial investment in regulatory capacity that may not be politically feasible.

The counter-signal reveals a deeper tension: constitutional accountability assumes that making power visible enables democratic oversight, but this assumes that democratic actors (regulators, civil society, researchers) have capacity to process information. When information volume exceeds processing capacity, transparency may become a form of opacity—burying important signals in noise. Digital Constitutionalism must either accept limits to transparency or advocate for massive investment in oversight infrastructure.

Stress Test: Algorithmic Public Health

This counter-signal is less problematic for Algorithmic Public Health, which routinely handles large datasets in epidemiological surveillance. The grammar views transparency overload as a data management challenge requiring computational tools, machine learning models, and visualization systems. Public health surveillance systems process millions of data points to identify patterns, trends, and emerging risks—the DSA Transparency Database is analogous.

Algorithmic Public Health's response is to advocate for better analytical infrastructure: automated anomaly detection, trend analysis, comparative dashboards, and risk scoring systems. The grammar views this as a technical problem with technical solutions. However, this response requires regulatory agencies to develop sophisticated data science capacity, which may be difficult given public sector resource constraints and competition with private sector for technical talent.

The counter-signal forces Algorithmic Public Health to confront the possibility that even with sophisticated analytical tools, the complexity of platform ecosystems may exceed comprehension. If platforms operate at scales and speeds that make comprehensive surveillance impossible, then evidence-based regulation may be fundamentally limited. The grammar must either accept partial observability or advocate for regulatory powers that slow platform operations to enable oversight—which platforms would resist as economically damaging.

Stress Test: Platform Realism

This counter-signal strongly supports Platform Realism's argument that content-focused transparency is misguided. The grammar views the DSA's granular moderation data as generating unusable information volumes because it focuses on individual content decisions rather than structural platform characteristics. Platform Realism advocates for transparency focused on market structure: ownership, revenue sources, algorithmic principles, interoperability capabilities—information that is more limited in volume but more relevant for assessing market power.

Platform Realism's response is to argue that transparency overload demonstrates the futility of content-focused regulation. If regulators cannot process transparency data, they cannot effectively oversee content moderation, making the entire regulatory approach ineffective. The grammar advocates for shifting to structural transparency that is more limited and processable.

However, this response may underestimate the value of granular data for research and civil society oversight, even if regulators cannot process it comprehensively. Academic researchers analyzing the DSA Transparency Database have generated important findings about platform behavior [2], [5], [15], [16], [23], [27]. Platform Realism must explain why structural transparency would be more valuable than enabling distributed oversight through public data access.

6.5 Counter-Signal 5: Jurisdictional Arbitrage and Regulatory Evasion

Empirical Content: Platforms can exploit jurisdictional differences by implementing minimal compliance in the EU while maintaining different practices elsewhere, or by restructuring operations to avoid VLOP designation. Territorial regulation of global platforms may be systematically evaded through corporate restructuring and strategic compliance [26].

Stress Test: Digital Constitutionalism

This counter-signal challenges Digital Constitutionalism's assumption that constitutional rights can be territorially enforced. If platforms can evade EU constitutional constraints by restructuring operations or implementing minimal compliance, then constitutional rights become geographically contingent and practically unenforceable. The grammar must confront the tension between territorial sovereignty and global platform operations.

Digital Constitutionalism's response is to advocate for extraterritorial application of constitutional principles, international coordination, or structural regulations that prevent evasion. The grammar argues that fundamental rights should apply to all users regardless of corporate structure or jurisdictional boundaries. However, this response faces legal and political challenges: extraterritorial regulation raises sovereignty concerns, international coordination is difficult given divergent constitutional traditions, and structural regulations may be beyond the scope of rights-based frameworks.

The counter-signal reveals a fundamental limitation: constitutional rights frameworks assume territorial sovereignty and state capacity to enforce rights within borders. When regulated entities are global and mobile, territorial enforcement may be inadequate. Digital Constitutionalism must either accept geographic limits to constitutional protections or advocate for global constitutional governance—a politically ambitious and legally complex project.

Stress Test: Algorithmic Public Health

This counter-signal challenges Algorithmic Public Health's assumption that harm reduction can be territorially regulated. If platforms implement different content policies in different jurisdictions, harms (disinformation, hate speech) may spread across borders, undermining territorial regulation. The grammar must confront the tension between territorial regulation and global information flows.

Algorithmic Public Health's response is to advocate for international coordination analogous to global health governance. Just as infectious diseases require coordinated international response, platform harms require coordinated regulatory approaches. The grammar advocates for evidence-based harm standards that transcend jurisdictions, international data sharing, and coordinated enforcement.

However, this response faces political challenges: countries have different cultural norms, legal traditions, and political systems that generate different views about what constitutes harmful content. International coordination on content standards may be impossible given these differences. Algorithmic Public Health must either accept jurisdictional fragmentation or advocate for global governance mechanisms that may not be politically feasible.

Stress Test: Platform Realism

This counter-signal is central to Platform Realism's analysis. The grammar views jurisdictional arbitrage as demonstrating that territorial regulation of global platforms is fundamentally limited. Platforms can restructure to evade jurisdiction, creating a structural advantage over territorial regulators. This dynamic gives platforms power over regulators, not just users.

Platform Realism's response is to advocate for structural interventions that cannot be evaded through jurisdictional restructuring: interoperability mandates (which benefit users regardless of platform location), data portability requirements (which reduce lock-in), or structural separation (which limits platform power directly). The grammar argues that these structural interventions are less vulnerable to arbitrage than content regulation.

However, this response may overstate the case. Even structural interventions require enforcement, which faces jurisdictional challenges. If a platform refuses to implement interoperability, how can a territorial regulator enforce compliance against a global entity? Platform Realism must explain why structural regulation is less vulnerable to jurisdictional arbitrage than content regulation, or accept that all territorial regulation of global platforms faces fundamental limits.

6.6 Synthesis: Grammar Resilience and Vulnerability

The stress testing reveals differential resilience across grammars:

Digital Constitutionalism is most vulnerable to Counter-Signals 1 (compliance as performance) and 5 (jurisdictional arbitrage), which challenge its assumptions about enforceability. The grammar's normative anchoring provides clarity but struggles when confronted with strategic actors and territorial limits.

Algorithmic Public Health is most vulnerable to Counter-Signals 2 (audit capture) and 4 (transparency overload), which challenge its evidence-based foundations. The grammar's reliance on reliable data and technical expertise is undermined when data is performative and auditors are captured.

Platform Realism is most resilient to counter-signals, which generally support its structural diagnosis. However, it is vulnerable to the critique that structural interventions are politically infeasible and temporally slow, leaving immediate governance failures unaddressed.

None of the grammars can fully resolve the counter-signals without abandoning core assumptions. This suggests that social media regulation faces fundamental challenges that cannot be solved within any single regulatory framework. Effective governance may require pragmatic combinations that accept trade-offs and limitations rather than seeking comprehensive solutions.

Section 7: Post-Analysis Reflexive Note

Temporal Position and Analytical Constraints

Writing in March 2026, this analysis captures social media regulation at a specific moment: the DSA's early implementation phase, characterized by database establishment, initial compliance reporting, and emerging empirical evidence about regulatory effectiveness. This temporal position creates both opportunities and constraints.

The opportunity is unprecedented empirical visibility. The DSA Transparency Database, launched September 2023, provides the most comprehensive dataset on content moderation ever assembled—353 million records in the first 100 days [2]. This enables empirical analysis that was impossible in earlier regulatory epochs. The signals identified in this analysis are grounded in actual platform behavior, not speculation or advocacy.

The constraint is temporal incompleteness. Thirty months of implementation (August 2023 to March 2026) is insufficient to assess long-term effects, adaptation dynamics, or unintended consequences. Platforms are still learning how to comply; regulators are still learning how to enforce; researchers are still learning how to analyze transparency data. The signals identified here may prove transient, while counter-signals dismissed by contemporary actors may prove structurally significant.

Grammar Identification as Interpretive Choice

The three regulatory grammars—Digital Constitutionalism, Algorithmic Public Health, Platform Realism—are analytical constructs, not natural kinds. The analyst identified these grammars by observing patterns in how different scholars, policymakers, and advocates organize evidence and generate prescriptions. However, other analysts might identify different grammars, subdivide these grammars further, or organize the observation field differently.

This raises a methodological question: are the grammars discovered or constructed? The Jazinski method treats grammars as real patterns in regulatory discourse—they exist independently of the analyst's observation. However, the analyst's choices about which patterns to emphasize, how to label them, and where to draw boundaries shape the analysis. The grammars are neither purely discovered nor purely constructed but emerge through interaction between regulatory discourse and analytical interpretation.

Counter-Signal Selection and Bias

The five counter-signals were selected to represent evidence that contradicts or undermines dominant regulatory narratives. However, the selection process involved judgment: which inconsistencies are significant enough to count as counter-signals versus mere implementation noise? The analyst prioritized counter-signals that challenge fundamental assumptions of regulatory grammars rather than tactical implementation details.

This selection process introduces potential bias. The analyst may have overlooked counter-signals that challenge assumptions the analyst shares, or emphasized counter-signals that align with the analyst's skepticism about regulatory effectiveness. The Jazinski method's requirement to identify counter-signals mitigates but cannot eliminate this bias.

Evidence Base Limitations

The analysis relies on 30 papers from a combined table of 297 sources, following the top-30 rule for relevance-ranked tables. This creates several limitations:

First, the evidence base is heavily weighted toward European regulation, particularly the DSA. Of the top 30 papers, 26 focus primarily on EU regulation, while only 4 substantively engage with U.S. developments. This geographic skew reflects the reality that the EU has produced more regulatory infrastructure to study, but it may overweight European regulatory logics while underrepresenting alternative approaches.

Second, the evidence base privileges academic scholarship over policy documents, industry reports, or civil society advocacy. This reflects the search strategy but may miss important signals visible in non-academic sources.

Third, the temporal scope (2016-2026) means that earlier regulatory history (Section 230's enactment in 1996, EU e-Commerce Directive in 2000) is treated as background rather than analyzed in detail. This may underestimate path dependencies and historical contingencies that shape contemporary regulation.

Contested Signal Interpretation

The three contested signals—automation as efficiency vs. rights violation, DSA database inconsistencies, Section 230 reform stalemate—were identified because they generate genuinely different interpretations across grammars. However, the analyst's presentation of these contested interpretations involves judgment about which interpretations are plausible and how to characterize them.

For example, Contested Signal 1 (automation) is presented as generating three interpretations (efficiency, rights violation, market response), but one could identify additional interpretations: automation as inevitable technological development, automation as labor displacement, automation as colonial imposition of Western content norms on global users. The analyst selected interpretations that map onto the three identified grammars, potentially obscuring other interpretive possibilities.

Normative Neutrality and Its Limits

The Jazinski method commits to treating regulatory grammars as sense-making systems to be understood rather than evaluated for correctness. The analyst attempted to present each grammar's logic sympathetically, showing how it processes signals coherently within its own framework. However, complete normative neutrality is impossible.

The analyst's language choices reveal subtle evaluative judgments. Describing Digital Constitutionalism's "normative anchoring" sounds more positive than describing its "rigidity." Describing Algorithmic Public Health's "evidence-based optimization" sounds more positive than describing its "technocratic recursion." Describing Platform Realism's "structural determinism" could be read as either parsimonious or reductionist.

These language choices reflect the analyst's embeddedness in academic discourse that values certain qualities (evidence-based reasoning, normative clarity, structural analysis) over others. The analysis cannot escape these evaluative frameworks but can make them visible through reflexive notation.

Practical Implications and Policy Relevance

This analysis was conducted as an academic exercise in regulatory interpretation, not as policy advocacy. However, it has practical implications:

For policymakers, the analysis reveals that regulatory debates are structured by incommensurable frameworks that cannot be empirically adjudicated. Policy choices involve selecting which grammar to privilege, not discovering which grammar is "correct." This suggests that effective regulation may require pragmatic combinations that accept trade-offs rather than seeking comprehensive solutions within a single framework.

For platforms, the analysis reveals that compliance strategies must navigate multiple regulatory logics simultaneously. The DSA embodies an unstable compromise across grammars, creating compliance complexity. Platforms that understand these underlying grammars may be better positioned to anticipate regulatory evolution.

For researchers, the analysis demonstrates the value of meta-level analysis that examines how regulatory discourse is structured rather than participating directly in advocacy. However, this meta-level stance risks appearing detached from urgent governance challenges, potentially reducing policy influence.

Future Trajectories and Analytical Limitations

The analysis identifies signals and counter-signals visible in March 2026 but cannot predict future regulatory trajectories. Several developments could fundamentally alter the observation field:

- Enforcement actions against major platforms for DSA violations, revealing regulatory teeth or weakness
- Platform restructuring to evade VLOP designation, testing jurisdictional limits
- Emergence of decentralized or federated platforms that challenge centralized regulation
- U.S. federal Section 230 reform, creating transatlantic regulatory divergence or convergence
- Algorithmic breakthroughs in content moderation, changing feasibility of automated governance
- Major platform-related harms (election interference, violence, mental health crisis), generating political pressure for regulatory change

Any of these developments could make signals identified here obsolete or elevate counter-signals to primary importance. The analysis is necessarily provisional, capturing a regulatory moment rather than a stable equilibrium.

Methodological Reflections on Jazinski Method

The Jazinski method's structured approach—observation field, signal compilation, grammar identification, signal processing, closure comparison, counter-signal stress testing—provided analytical discipline. The requirement to identify counter-signals and contested signals forced the analyst to look for evidence that contradicts dominant narratives rather than confirming them.

However, the method's structure also creates constraints. The requirement to identify exactly 15 primary signals, 5 counter-signals, and 3 contested signals is somewhat arbitrary—the observation field might naturally generate different numbers. The requirement to identify exactly 3 grammars similarly constrains analysis—one could identify 2, 4, or 5 grammars depending on how finely to subdivide regulatory logics.

The method's emphasis on closure comparison and stress testing is valuable for revealing how different frameworks maintain coherence and respond to challenges. However, this emphasis on internal coherence may underweight the importance of pragmatic effectiveness. A grammar that is internally coherent but practically ineffective may be less valuable than a pragmatic approach that is theoretically messy but empirically successful.

Final Reflexive Observation

This analysis is itself embedded in the regulatory discourse it analyzes. By identifying and naming regulatory grammars, the analysis may reify them, making them appear more distinct and stable than they are in practice. Actual regulatory debates involve hybrid positions, strategic ambiguity, and pragmatic compromises that don't fit neatly into the three grammars identified here.

The analysis is also temporally situated in a moment of regulatory experimentation and uncertainty. Future observers may view the 2016-2026 period as a transitional phase between the "intermediary liability" paradigm (1996-2016) and some future paradigm not yet visible. The grammars identified here may prove to be transitional sense-making systems rather than stable regulatory frameworks.

Despite these limitations, the analysis provides value by making visible the interpretive structures that organize regulatory debate. By showing how the same empirical signals generate different regulatory prescriptions depending on which grammar is applied, the analysis reveals that regulatory disagreements

are often not about facts but about frameworks. This meta-level understanding may enable more productive regulatory debates that explicitly address framework choices rather than arguing past each other within incommensurable frameworks.

Section 8: Methodological Observations

8.1 Jazinski Method Application

Structural Fidelity

This analysis followed the Jazinski method's prescribed structure: Step 0 (Reflexive Declaration), Section 1 (Observation Field), Section 2 (Signal Compilation with 15 primary, 5 counter, 3 contested signals), Section 3 (Grammar Identification), Section 4 (Signal Processing with 1,000-1,500 word essays per grammar), Section 5 (Closure Comparison), Section 6 (Counter-Signal Stress Testing), Section 7 (Post-Analysis Reflexive Note), and Section 8 (Methodological Observations).

The method's structured approach provided analytical discipline, forcing systematic examination of evidence, explicit identification of interpretive frameworks, and rigorous stress testing of each framework against counter-evidence. The requirement to identify counter-signals and contested signals prevented confirmation bias, ensuring that the analysis engaged with evidence that contradicts dominant regulatory narratives.

Adaptations and Constraints

The method was designed for analyzing scientific or technical controversies, not regulatory policy. This required adaptations:

- The "observation field" was interpreted as the regulatory discourse and empirical evidence base rather than a laboratory or field site.
- "Signals" were interpreted as empirical findings, policy developments, and regulatory outcomes rather than experimental results.
- "Grammars" were interpreted as regulatory frameworks rather than scientific paradigms.

These adaptations maintained the method's core logic (examining how different interpretive frameworks process the same evidence) while applying it to a policy domain. However, regulatory policy differs from scientific controversy in important ways: it involves normative commitments (not just empirical claims), power dynamics (not just epistemic disputes), and practical constraints (not just theoretical coherence). The method's emphasis on interpretive frameworks translated well, but its assumption of eventual empirical resolution may not apply to normative regulatory debates.

8.2 Evidence Base Characteristics

Source Composition

The analysis drew on 30 papers from a relevance-ranked combined table of 297 sources. The evidence base exhibited several characteristics:

- Geographic concentration: 87% of top 30 papers focused primarily on EU regulation, particularly the DSA.
- Temporal concentration: 73% were published 2023-2026, reflecting the DSA's implementation phase.

- Disciplinary diversity: Papers spanned law, computer science, communication studies, political science, and policy analysis.
- Methodological diversity: Included empirical audits of DSA database [2], [15], [16], legal analysis [3], [11], [30], policy evaluation [12], [13], conceptual frameworks [7], [17], and mixed methods [5], [23], [29].

This composition enabled rich analysis of DSA implementation but limited analysis of alternative regulatory approaches (U.S. Section 230, decentralized platforms, non-Western regulation). The evidence base was strongest on transparency and content moderation, weaker on market structure and competition.

Data Infrastructure Significance

The DSA Transparency Database, launched September 2023, fundamentally changed the evidentiary landscape. Multiple papers in the top 30 analyzed this database [2], [5], [10], [15], [16], [23], [27], generating unprecedented empirical visibility into platform content moderation. This created a "before and after" dynamic: pre-2023 scholarship relied on voluntary transparency reports and limited platform data; post-2023 scholarship could analyze comprehensive regulatory data.

However, this data infrastructure also shaped what could be known. The database's structure, categories, and reporting requirements determined what became visible. Papers analyzing the database consistently identified data quality issues, inconsistencies, and structural inadequacies [2], [5], [10], suggesting that the database is simultaneously a breakthrough in transparency and a contested evidentiary artifact.

8.3 Grammar Identification Process

Inductive vs. Deductive

The three regulatory grammars were identified through iterative interaction between the evidence base and theoretical frameworks. The process was neither purely inductive (discovering grammars in the data) nor purely deductive (applying pre-existing frameworks) but abductive (inferring grammars as best explanations for observed patterns).

The analyst began with theoretical familiarity with constitutional law, public health regulation, and political economy, then observed how papers in the evidence base organized arguments, processed evidence, and generated prescriptions. Patterns emerged: some papers emphasized rights and process [11], [17], [30], others emphasized harm reduction and risk [2], [6], [12], [13], [14], others emphasized market structure [7], [26]. These patterns were formalized into the three grammars.

Alternative Grammar Possibilities

Other analysts might identify different grammars. Possible alternatives include:

- Technological Solutionism: Viewing regulation as requiring technical fixes (better AI, improved detection systems, platform design changes) rather than legal or structural interventions.
- Democratic Governance: Emphasizing participatory decision-making, community self-governance, and democratic legitimacy rather than expert-driven regulation.
- Geopolitical Competition: Viewing regulation as instrument of geopolitical competition between U.S. and EU, or between democratic and authoritarian regimes.
- Deregulatory Libertarianism: Advocating minimal regulation, emphasizing platform innovation and user choice over state intervention.

These alternative grammars exist in regulatory discourse but were less prominent in the top 30 papers. The analyst's choice to focus on Digital Constitutionalism, Algorithmic Public Health, and Platform Realism

reflected their prominence in the evidence base and their analytical distinctiveness, but involved judgment about which patterns to emphasize.

8.4 Signal Processing Methodology

Integration of Counter-Signals

The Jazinski method requires integrating counter-signals during signal processing, not treating them as separate. This was implemented by having each grammar process counter-signals within Section 4 (Signal Processing), showing how each grammar responds to contradictory evidence. Section 6 (Counter-Signal Stress Testing) then systematically examined whether these responses are adequate or reveal fundamental limitations.

This approach revealed how grammars maintain coherence when confronted with counter-evidence: Digital Constitutionalism advocates for stronger procedural protections, Algorithmic Public Health demands better evidence and refined interventions, Platform Realism reframes counter-signals as supporting structural diagnosis. These closure mechanisms are not arbitrary but reflect each grammar's core logic.

Contested Signal Treatment

The three contested signals were identified because they generate genuinely different interpretations across grammars, not just disagreements about emphasis. Contested Signal 1 (automation) is interpreted as efficiency by Algorithmic Public Health, rights violation by Digital Constitutionalism, and market response by Platform Realism—these are incommensurable interpretations, not reconcilable differences.

Treating these signals as contested rather than simply ambiguous revealed that regulatory disagreements often stem from framework differences rather than factual disputes. The same empirical fact (92% automation rate) supports contradictory regulatory prescriptions depending on which grammar is applied. This suggests that resolving regulatory debates requires explicit framework choices, not just better evidence.

8.5 Analytical Limitations and Boundary Conditions

Temporal Limitations

The analysis captures regulation in March 2026, during the DSA's early implementation phase. This creates several limitations:

- Insufficient time for long-term effects: Thirty months of implementation is too short to assess whether the DSA achieves its goals, generates unintended consequences, or prompts platform adaptation.
- Implementation artifacts: Early compliance patterns may not represent stable equilibria; platforms and regulators are still learning.
- Incomplete enforcement: Major enforcement actions may not yet have occurred, making it difficult to assess regulatory teeth.

Future analysis in 2028 or 2030 might identify different signals, find that counter-signals became primary, or observe grammar evolution as regulatory reality becomes clearer.

Geographic Limitations

The evidence base's European concentration means the analysis may overweight EU regulatory logics while underrepresenting alternative approaches. U.S. Section 230 debates, Chinese social credit systems, Indian intermediary liability rules, and Brazilian regulatory experiments receive limited attention. This

creates potential bias toward viewing comprehensive regulatory frameworks (like the DSA) as more "advanced" than alternative approaches.

Disciplinary Limitations

The evidence base privileges academic scholarship, particularly legal and policy analysis. This may miss important signals visible in:

- Industry sources: Platform transparency reports, corporate communications, technical documentation
- Civil society sources: Advocacy organization reports, user testimonials, community governance experiments
- Regulatory sources: Enforcement actions, guidance documents, regulatory agency reports
- Journalistic sources: Investigative reporting on platform practices, regulatory politics, enforcement challenges

A more comprehensive analysis would integrate these sources, potentially identifying additional signals or alternative grammars.

8.6 Comparative Insights Across Grammars

Incommensurability

The analysis revealed that the three grammars are incommensurable: they employ different evidence standards, operate on different temporal horizons, and generate incompatible prescriptions. This incommensurability means that regulatory debates often involve talking past each other rather than genuine disagreement about shared questions.

Digital Constitutionalism asks "Are individual rights protected?" Algorithmic Public Health asks "Is aggregate harm reduced?" Platform Realism asks "Is market structure changed?" These are different questions, not different answers to the same question. A regulation can succeed by one grammar's standards while failing by another's.

This incommensurability has practical implications: regulatory policy cannot satisfy all grammars simultaneously without internal contradiction. The DSA attempts an unstable compromise, incorporating elements of all three grammars without fully committing to any. This may generate implementation challenges as different provisions pull in different directions.

Closure Mechanisms

Each grammar maintains coherence through characteristic closure mechanisms:

- Digital Constitutionalism: Normative anchoring in constitutional principles; recursive expansion of procedural protections
- Algorithmic Public Health: Evidence-based optimization; technocratic recursion demanding better measurement and refined interventions
- Platform Realism: Structural determinism; reframing all problems as symptoms of market concentration

These closure mechanisms provide stability but also rigidity. Each grammar has difficulty processing evidence that challenges its core assumptions, instead assimilating counter-signals into its existing framework. This suggests that regulatory learning may be difficult: grammars resist fundamental revision even when confronted with contradictory evidence.

Pragmatic Synthesis Challenges

The analysis revealed that pragmatic synthesis across grammars is difficult without abandoning core commitments. Attempts to combine grammars generate contradictions:

- Mandating human review (Digital Constitutionalism) conflicts with embracing automation (Algorithmic Public Health)
- Focusing on content moderation (Digital Constitutionalism, Algorithmic Public Health) conflicts with viewing content regulation as misguided (Platform Realism)
- Prioritizing individual rights (Digital Constitutionalism) conflicts with utilitarian harm reduction (Algorithmic Public Health)

Effective regulation may require accepting these contradictions and making explicit trade-offs rather than seeking theoretical coherence. However, this pragmatic approach lacks the normative clarity and analytical coherence that each grammar provides, potentially making it politically vulnerable and difficult to implement consistently.

8.7 Methodological Contributions

Meta-Level Analysis Value

The Jazinski method's emphasis on meta-level analysis—examining how regulatory discourse is structured rather than participating directly in advocacy—provided several benefits:

- Revealed hidden assumptions: Made visible the interpretive frameworks that structure regulatory debate
- Explained persistent disagreements: Showed that disagreements often stem from framework differences rather than factual disputes
- Identified incommensurability: Demonstrated that some regulatory debates cannot be resolved empirically because they involve incommensurable frameworks
- Enabled systematic comparison: Provided structured method for comparing how different frameworks process the same evidence

However, this meta-level stance also has costs: it may appear detached from urgent governance challenges, potentially reducing policy influence. Policymakers may prefer clear prescriptions over analytical complexity.

Reflexivity Requirements

The method's requirement for reflexive declarations (Step 0, Section 7) forced explicit acknowledgment of analyst position, biases, and limitations. This reflexivity is valuable for scholarly integrity but also reveals the impossibility of neutral analysis. The analyst is embedded in the regulatory discourse being analyzed, shaped by the same conceptual vocabularies and normative commitments.

Reflexivity cannot eliminate bias but can make it visible, enabling readers to assess how analyst position shapes interpretation. This is particularly important for policy-relevant research where analytical choices have practical implications.

Replicability and Transparency

The method's structured approach enhances replicability: another analyst following the same method with the same evidence base should identify similar patterns, though potentially with different emphases or labels. The requirement to explicitly identify signals, grammars, and processing logic makes analytical choices transparent and contestable.

However, complete replicability is impossible because grammar identification involves interpretive judgment. Different analysts might identify different grammars, subdivide grammars differently, or

emphasize different aspects of each grammar. The method provides structure but cannot eliminate interpretive discretion.

8.8 Future Research Directions

Longitudinal Analysis

This analysis captures a single temporal moment (March 2026). Future research should conduct longitudinal analysis tracking how signals, counter-signals, and grammars evolve over time. Key questions include:

- Do early implementation signals prove stable or transient?
- Do counter-signals become more prominent as regulatory limitations become apparent?
- Do grammars evolve in response to empirical evidence, or remain stable despite contradictory findings?
- Does one grammar become dominant in policy, or does regulatory discourse remain pluralistic?

Comparative Jurisdictional Analysis

This analysis focused primarily on EU regulation due to evidence base composition. Future research should conduct systematic comparison across jurisdictions:

- How do U.S., EU, Chinese, Indian, and Brazilian regulatory approaches differ?
- Do different jurisdictions privilege different grammars?
- How do platforms navigate compliance across divergent regulatory regimes?
- Does regulatory competition generate convergence or divergence over time?

Alternative Grammar Exploration

This analysis identified three grammars prominent in the evidence base. Future research should explore alternative grammars that may be less prominent in academic scholarship but influential in policy or practice:

- Technological solutionism in platform engineering communities
- Democratic governance in civil society advocacy
- Geopolitical competition in international relations
- Deregulatory libertarianism in industry lobbying

Enforcement and Implementation Studies

This analysis focused on regulatory design and early implementation. Future research should examine enforcement dynamics:

- How do regulatory authorities exercise discretion in enforcement?
- What factors determine which platforms or violations are prioritized?
- How do platforms respond strategically to enforcement actions?
- What are the practical limits of regulatory capacity?

User and Community Perspectives

This analysis privileged regulatory and platform perspectives. Future research should center user and community perspectives:

- How do users experience content moderation under different regulatory regimes?
- Do transparency mandates actually empower users or generate information overload?

- How do marginalized communities navigate platform governance?
- What alternative governance models (community moderation, federated systems) exist?

8.9 Practical Implications for Policy

Framework Choice Necessity

The analysis demonstrates that effective regulation requires explicit framework choices. Policymakers cannot avoid choosing which grammar to privilege because attempting to satisfy all grammars simultaneously generates internal contradictions. The DSA's attempt at comprehensive synthesis creates implementation complexity and potential incoherence.

Explicit framework choice enables:

- Clearer regulatory goals: Defining success criteria based on chosen framework
- Consistent implementation: Aligning enforcement with framework logic
- Honest trade-offs: Acknowledging what is sacrificed by choosing one framework over others
- Accountability: Enabling evaluation based on framework-appropriate metrics

Pragmatic Combination Strategies

While comprehensive synthesis is impossible, pragmatic combinations may be feasible:

- Layered regulation: Different grammars for different regulatory domains (rights for individual decisions, public health for systemic risks, realism for market structure)
- Sequential regulation: Different grammars for different temporal phases (immediate rights protections, medium-term harm reduction, long-term structural change)
- Jurisdictional variation: Different grammars in different jurisdictions based on constitutional traditions and political preferences

These pragmatic approaches accept theoretical incoherence in exchange for practical effectiveness, but require careful design to avoid contradictory requirements.

Regulatory Humility

The analysis reveals fundamental limitations in all regulatory approaches:

- Digital Constitutionalism struggles with scale and strategic compliance
- Algorithmic Public Health faces measurement challenges and normative contestation
- Platform Realism confronts political feasibility and temporal constraints

This suggests the need for regulatory humility: acknowledging that no regulatory approach can comprehensively solve platform governance challenges. Effective regulation may require:

- Iterative experimentation: Testing approaches, learning from failures, adapting based on evidence
- Distributed governance: Combining state regulation, platform self-governance, and community moderation
- Explicit trade-offs: Acknowledging that improving some outcomes may worsen others
- Realistic expectations: Accepting that platform governance will remain contested and imperfect

8.10 Conclusion

The Jazinski method provided valuable analytical structure for examining social media regulation through multiple interpretive frameworks. The method's emphasis on signal compilation, grammar identification,

systematic processing, and counter-signal stress testing revealed how regulatory discourse is structured by incommensurable frameworks that process the same evidence into incompatible prescriptions.

The analysis demonstrated that regulatory disagreements often stem from framework differences rather than factual disputes, suggesting that effective policy requires explicit framework choices and honest acknowledgment of trade-offs. The method's reflexive requirements forced recognition of analytical limitations and temporal contingency, enhancing scholarly integrity while revealing the impossibility of neutral analysis.

Future research should extend this approach through longitudinal analysis, comparative jurisdictional studies, and exploration of alternative grammars. The method's structured approach and emphasis on meta-level analysis provide valuable tools for understanding complex, contested policy domains where multiple interpretive frameworks compete for influence.
